

# Microscopic Models for Mobile Anyons from Fusion Categories

Tobias J. Osborne

January 3, 2026

## Abstract

We develop a systematic framework for constructing microscopic lattice models describing mobile (itinerant) anyons arising from an arbitrary fusion category. Unlike existing models such as the golden chain where anyons are fixed at predetermined positions, our framework allows both the positions and number of anyons to fluctuate dynamically. Working in a first-quantised formalism on a one-dimensional chain with open boundary conditions, we construct Hilbert spaces that accommodate variable anyon number and anyon mobility, and define microscopic Hamiltonians for physically motivated scenarios. The framework is validated by reduction to known limiting cases including standard bosonic/fermionic systems and tightly-packed fusion chains.

# 1 Introduction

## 1.1 Why Mobile Anyons?

Anyonic particles—quasiparticle excitations obeying exotic exchange statistics that interpolate between bosonic and fermionic behaviour—have become central objects of study in condensed matter physics and quantum information theory. The mathematical framework of fusion categories provides a rigorous foundation for describing systems of anyons, encoding their fusion rules, braiding statistics, and algebraic structure in a unified formalism [Kit06, ENO05].

Existing microscopic many-body models based on fusion categories, such as the celebrated golden chain [FTLM07], describe systems where anyons occupy fixed positions on a lattice. In such models, the number of anyons is constant and their positions are predetermined—analogous to the tightly-packed Mott insulating phase in condensed matter systems. While these models have yielded profound insights into anyonic physics, including connections to conformal field theory at criticality, they represent only a special limiting case of the broader landscape of possible anyonic phases.

In realistic physical systems, however, particle number and position are typically dynamical degrees of freedom. Electrons in metals move freely through the lattice; ultracold atoms in optical lattices tunnel between sites; quasiparticles in quantum Hall systems can be created, annihilated, and transported. A complete understanding of anyonic matter requires extending the categorical framework to accommodate such *mobile* or *itinerant* anyons.

The motivation for developing microscopic models of mobile anyons is threefold:

- (i) **Connection to realistic physics.** Physical systems supporting anyonic excitations—such as fractional quantum Hall states or topological superconductors—generically allow for variable anyon number and mobility. Microscopic models capturing these features would bridge the gap between abstract categorical data and experimentally accessible phenomena including transport, scattering, and thermodynamic properties.
- (ii) **Exploration of new phases.** Beyond the Mott-like limit of fixed anyons, one expects a rich phase diagram including dilute anyonic gases, anyonic superfluids, and intermediate correlated phases. The interplay between anyonic exchange statistics and spatial dynamics may give rise to novel collective phenomena without analogue in conventional bosonic or fermionic systems.
- (iii) **Recovery of known limits.** A consistent framework must reproduce well-understood special cases. When fusion rules are trivial ( $X \otimes X = \mathbf{1}$ ), we should recover ordinary bosons or fermions depending on the braiding structure. For super-vector spaces (sVec), the construction should reduce exactly to fermionic Fock space with standard anticommutation relations. For dense configurations, we should recover the physics of the golden chain and related models.

The present work addresses this gap by developing a systematic framework for constructing microscopic lattice models describing mobile anyons arising from an arbitrary fusion category. Working in a first-quantised formalism on a one-dimensional chain with open boundary conditions, we construct Hilbert spaces that accommodate variable anyon number and anyon mobility, and define microscopic Hamiltonians for physically motivated scenarios.

## 1.2 Literature Gap

The theoretical study of anyonic systems has developed along two largely disjoint lines. On the mathematical side, the theory of fusion categories [ENO05, EGNO15] provides a complete algebraic framework for describing anyon types, their fusion rules, and braiding statistics. This

framework is abstract and basis-independent, applicable to any system whose excitations form a fusion category. On the physical side, microscopic lattice models—most prominently the golden chain [FTLM07] and its generalisations—have demonstrated how to construct explicit Hamiltonians whose low-energy physics is governed by anyonic degrees of freedom.

However, these microscopic models invariably assume a *dense* configuration: one anyon occupies each lattice site, and the Hilbert space is spanned by the different ways adjacent anyons can fuse. This corresponds to a Mott-insulating regime where particle number is maximal and fixed, and spatial dynamics are frozen out. The only degrees of freedom are the internal fusion channels—essentially, which superselection sector the system occupies locally.

Several important physical questions lie outside this dense limit:

- **Dilute anyonic gases.** What is the ground state of a system with fewer anyons than sites? How do anyonic statistics affect spatial correlations in a dilute gas?
- **Hopping and transport.** If anyons can tunnel between sites, how does the interplay of mobility and exotic statistics manifest in transport properties?
- **Variable particle number.** Can we define pair-creation and annihilation processes consistent with fusion rules? What phases emerge when particle number fluctuates?
- **Interpolation to known limits.** A framework for mobile anyons should reduce to standard fermionic or bosonic physics when the fusion category is trivial (sVec or Vec respectively), providing a consistency check and physical intuition.

To our knowledge, no systematic framework exists for constructing microscopic lattice models of mobile anyons arising from a general fusion category. The present work aims to fill this gap.

### 1.3 Contributions of This Work

This paper develops a systematic framework for mobile anyons on a one-dimensional lattice, making the following contributions:

- (1) **First-quantised Fock space construction.** We construct Hilbert spaces  $\mathcal{H}_N^{(c)}$  for  $N$  anyons with total charge  $c$ , built from morphism spaces of the underlying fusion category. The total Hilbert space  $\mathcal{H} = \bigoplus_N \mathcal{H}_N$  accommodates variable particle number without invoking second-quantised creation/annihilation operators.
- (2) **Configuration space formalism.** We define labelled configurations  $(\mathbf{j}, \mathbf{k})$  specifying both positions and anyon types, with careful treatment of hard-core (at most one anyon per site) and soft-core (multiple occupancy allowed) constraints.
- (3) **Local operator algebra.** We characterise the space of  $k$ -local operators—those acting nontrivially on at most  $k$  consecutive sites—in terms of morphisms between tensor products of simple objects. This provides the building blocks for physically motivated Hamiltonians.
- (4) **Explicit matrix elements.** For 2-local operators, we derive matrix element formulas in the fusion tree basis, expressing hopping, interaction, and braiding terms in terms of the category's F-symbols.
- (5) **Recovery of standard limits.** We verify that when specialised to sVec (super-vector spaces), the construction reduces exactly to fermionic Fock space with the correct anti-commutation relations and Jordan–Wigner structure.
- (6) **Boundary conditions via module categories.** We show how module categories over  $\mathcal{C}$  naturally encode boundary conditions, connecting the bulk categorical data to edge physics.

## 1.4 Paper Outline

The remainder of this paper is organised as follows.

**Part I: Preliminaries** establishes the mathematical and physical foundations. We review fusion rings and fusion categories, emphasising morphism spaces and the role of F-symbols as the fundamental structural data. We discuss the diagrammatic calculus for morphisms and present key examples including Fibonacci, Ising, and Temperley–Lieb categories. We then review standard Fock space constructions for bosons and fermions in first-quantised language, and fix conventions for lattice geometry.

**Part II: Hilbert Space for Mobile Anyons** develops the core construction. We define the configuration space for  $N$  anyons on an  $L$ -site chain, carefully distinguishing hard-core (exclusion) and soft-core (multiple occupancy) variants. The Hilbert space  $\mathcal{H}_N^{(c)}$  for  $N$  anyons with total charge  $c$  is constructed as a direct sum over configurations, with each summand given by the appropriate morphism space in  $\mathcal{C}$ . We characterise the space of local operators and develop a basis-independent framework for their action.

**Part III: Dynamics** constructs explicit Hamiltonians. We derive matrix element formulas for 2-local operators in the fusion tree basis, expressing hopping, on-site interactions, and nearest-neighbour braiding in terms of F-symbols. We then define particle-number-conserving Hamiltonians including kinetic (hopping) terms and anyonic generalisations of the Hubbard interaction.

**Part IV: Basic Properties** analyses the constructed models. We show how module categories over  $\mathcal{C}$  encode boundary conditions, connecting bulk categorical data to edge physics. We verify reduction to fermionic Fock space for sVec and to the golden chain in the dense limit.

We conclude with a discussion of open problems and future directions, including extensions to higher dimensions, incorporation of symmetries, and connections to topological field theory.

# Part I

## Preliminaries

### 2 Fusion Ring

**Assumptions.**

- (A1) Finite set of simple objects  $\{X_i\}_{i=0}^{d_{\mathcal{C}}-1}$ .
- (A2) Structure constants  $N_{ab}^c \in \mathbb{Z}_{\geq 0}$  are associative and unital with unit **1**.

#### 2.1 Simple Objects

**Definition 2.1** (Simple object). Let  $\mathcal{C}$  be an abelian category. An object  $X \in \mathcal{C}$  is *simple* if it has exactly two subobjects: 0 and  $X$  itself. Equivalently,  $X \neq 0$  and every monomorphism  $Y \hookrightarrow X$  is either zero or an isomorphism.

*Remark 2.2.* In a semisimple category, an object is simple if and only if it is nonzero and indecomposable (cannot be written as  $X \cong Y \oplus Z$  with  $Y, Z \neq 0$ ).

**Lemma 2.3** (Schur’s lemma). *In a  $k$ -linear abelian category with  $k$  algebraically closed, if  $X$  is simple then  $\text{End}(X) \cong k$ . That is, every endomorphism of a simple object is a scalar multiple of the identity.*

*Consequence 2.4.* By semisimplicity of fusion categories (Deligne's theorem), every object  $A \in \mathcal{C}$  decomposes as a finite direct sum of simple objects:

$$A \cong \bigoplus_{i \in I} X_i^{\oplus m_i} \quad (1)$$

where  $X_i$  are simple and  $m_i \in \mathbb{Z}_{\geq 0}$  are multiplicities.

*Remark 2.5.* For our purposes, we work with fusion categories where the simple objects are *distinguishable* by their labels:  $\{X_0, X_1, \dots, X_{d_C-1}\}$  with  $X_0 = \mathbf{1}$  (the tensor unit/vacuum).

*Reference:* Etingof–Gelaki–Nikshych–Ostrik, *Tensor Categories*, AMS (2015), Def. 1.5.1 [EGNO15] [unverified]

## 2.2 Fusion Ring Definition

**Definition 2.6** (Fusion ring). A *fusion ring* is a finitely generated free abelian group  $R = \bigoplus_{i \in I} \mathbb{Z} X_i$  with a ring structure satisfying:

1.  $X_0 = \mathbf{1}$  is the unit element.
2. The product of basis elements satisfies

$$X_i X_j = \sum_{k \in I} N_{ij}^k X_k, \quad (2)$$

where  $N_{ij}^k \in \mathbb{Z}_{\geq 0}$  are the *fusion coefficients* (or fusion multiplicities).

3. There exists an involution  $i \mapsto i^*$  such that

$$N_{ij}^0 = \delta_{i,j^*}. \quad (3)$$

The involution gives duality:  $X_i^* = X_{i^*}$ . Associativity follows from the ring axioms:

$$\sum_e N_{ij}^e N_{ek}^\ell = \sum_e N_{jk}^e N_{ie}^\ell \quad \text{for all } i, j, k, \ell \in I. \quad (4)$$

*Remark 2.7.* Fusion rings are generally *not commutative*, i.e.,  $N_{ij}^k \neq N_{ji}^k$  in general.

*Reference:* Etingof–Gelaki–Nikshych–Ostrik, *Tensor Categories*, AMS (2015), §3.1 [EGNO15] [unverified]

## 3 Fusion Categories

### Assumptions.

- (A3.1.2.1) Fusion ring  $(R, \{X_i\}_{i \in I}, \mathbf{1})$  with  $X_0 = \mathbf{1}$  and  $N_{ij}^k \in \mathbb{Z}_{\geq 0}$  (Definition 2.6).
- (A3.1.2.2) Associator data  $F$  (and, when present, braiding data  $R$ ) satisfy the pentagon/hexagon equations.

**Definition 3.1** (Fusion category). A *fusion category* over an algebraically closed field  $k$  (usually  $k = \mathbb{C}$ ) is a  $k$ -linear, semisimple, rigid monoidal category

$$(\mathcal{C}, \otimes, \mathbf{1}) \quad (5)$$

satisfying the following conditions:

1. **Finiteness:** There are finitely many isomorphism classes of simple objects. Every object decomposes as a finite direct sum of simples.
2. **Semisimplicity:** All morphism spaces  $\text{Mor}(X, Y)$  are finite-dimensional  $k$ -vector spaces, and the category is abelian and semisimple.
3. **Rigidity:** Every object  $X \in \mathcal{C}$  has a left and right dual  $X^*$  with evaluation and coevaluation morphisms satisfying the rigidity axioms (Definition 3.2).
4. **Simple unit:** The tensor unit  $\mathbf{1}$  is simple:  $\text{End}(\mathbf{1}) \cong k$ .
5. **Finite  $k$ -linearity:** The monoidal structure is bilinear over  $k$ , and composition and tensor product of morphisms are  $k$ -linear.

**Definition 3.2** (Rigidity axioms). For an object  $X$  with dual  $X^*$ , the *evaluation*  $\text{ev}_X : X^* \otimes X \rightarrow \mathbf{1}$  and *coevaluation*  $\text{coev}_X : \mathbf{1} \rightarrow X \otimes X^*$  morphisms must satisfy the *rigidity axioms* (zigzag identities):

$$(\text{ev}_X \otimes \text{id}_X) \circ (\text{id}_{X^*} \otimes \text{coev}_X) = \text{id}_X \quad (6)$$

$$(\text{id}_{X^*} \otimes \text{ev}_X) \circ (\text{coev}_X \otimes \text{id}_{X^*}) = \text{id}_{X^*} \quad (7)$$

Diagrammatically, these are the “straightening” of a bent string (cup followed by cap yields identity).

**Definition 3.3** (Simple objects of a category). For a fusion category  $\mathcal{C}$ , we denote by  $\text{Irr}(\mathcal{C})$  the set of isomorphism classes of simple objects. We write  $[X] \in \text{Irr}(\mathcal{C})$  for the isomorphism class containing simple object  $X$ .

**Definition 3.4** (Quantum dimension). For a simple object  $X$  in a fusion category  $\mathcal{C}$ , the *quantum dimension*  $d_X$  is defined via the categorical trace:

$$d_X = \text{tr}(\text{id}_X) = \text{ev}_X \circ (\text{id}_{X^*} \otimes \text{coev}_{X^*}) \circ \text{coev}_X \quad (8)$$

Diagrammatically,  $d_X$  is the value of a closed loop labelled by  $X$ . For the tensor unit,  $d_{\mathbf{1}} = 1$ . The *total dimension* of the category is  $\dim(\mathcal{C}) = \sum_{X \in \text{Irr}(\mathcal{C})} d_X^2$ .

*Remark 3.5.* Quantum dimensions satisfy  $d_X d_Y = \sum_Z N_{XY}^Z d_Z$  (compatible with fusion rules) and  $d_X = d_{X^*}$ . For unitary categories,  $d_X \geq 1$  with equality iff  $X$  is invertible.

**Definition 3.6** (Skeletal category). A category is *skeletal* if isomorphic objects are equal:  $X \cong Y$  implies  $X = Y$ . Every category is equivalent to a skeletal one, and for fusion categories we often work with a skeletal representative where the simple objects are  $\{X_0, X_1, \dots, X_{d-1}\}$  with  $X_0 = \mathbf{1}$ .

**Definition 3.7** (Grothendieck ring). From any fusion category  $\mathcal{C}$ , we construct its *Grothendieck ring*  $K_0(\mathcal{C})$  by

$$K_0(\mathcal{C}) = \bigoplus_{[X] \in \text{Irr}(\mathcal{C})} \mathbb{Z}[X], \quad (9)$$

with multiplication

$$[X] \cdot [Y] = \sum_Z N_{XY}^Z [Z], \quad (10)$$

where  $N_{XY}^Z = \dim_k \text{Mor}(X \otimes Y, Z)$  is the fusion multiplicity. The Grothendieck ring  $K_0(\mathcal{C})$  is a fusion ring (Definition 2.6), establishing that *fusion categories categorify fusion rings*.

**Definition 3.8** (Braided fusion category). If additionally  $\mathcal{C}$  is equipped with a braiding (natural isomorphisms  $c_{X,Y} : X \otimes Y \rightarrow Y \otimes X$  satisfying hexagon identities), we call  $\mathcal{C}$  a *braided fusion category*.

*Reference:* Etingof–Gelaki–Nikshych–Ostrik, *Tensor Categories*, AMS (2015), Ch. 4 and Ch. 8 [EGNO15] [unverified]

### 3.1 F-Symbols and Pentagon Equation

**Definition 3.9** (F-symbols). The *associator* is a natural isomorphism

$$\alpha_{a,b,c} : (a \otimes b) \otimes c \xrightarrow{\sim} a \otimes (b \otimes c) \quad (11)$$

that satisfies the pentagon equation (Definition 3.11). In a skeletal category (Definition 3.6), the associator is determined by its matrix elements, the *F-symbols*.

For simple objects  $a, b, c, d$ , the isomorphism decomposes into blocks indexed by intermediate fusion channels  $e$  (for  $(a \otimes b) \rightarrow e \rightarrow d$ ) and  $f$  (for  $(b \otimes c) \rightarrow f \rightarrow d$ ). The change of basis is given by the *F-move*:

$$|(a \otimes b) \otimes c \rightarrow d; e, \alpha, \beta\rangle = \sum_{f, \mu, \nu} (F_{abc}^d)_{e, \alpha, \beta}^{f, \mu, \nu} |a \otimes (b \otimes c) \rightarrow d; f, \mu, \nu\rangle \quad (12)$$

where  $\alpha, \beta, \mu, \nu$  are *multiplicity indices*.

*Remark 3.10* (Multiplicity indices). The indices  $\alpha, \beta, \mu, \nu$  label basis vectors within fusion spaces when fusion multiplicities  $N_{ab}^c > 1$ . Specifically:

- $\alpha \in \{1, \dots, N_{ab}^e\}$  labels basis morphisms in  $\text{Mor}(a \otimes b, e)$
- $\beta \in \{1, \dots, N_{ec}^d\}$  labels basis morphisms in  $\text{Mor}(e \otimes c, d)$
- $\mu \in \{1, \dots, N_{bc}^f\}$  labels basis morphisms in  $\text{Mor}(b \otimes c, f)$
- $\nu \in \{1, \dots, N_{af}^d\}$  labels basis morphisms in  $\text{Mor}(a \otimes f, d)$

For *multiplicity-free* categories (where all  $N_{ab}^c \in \{0, 1\}$ ), these indices are trivial and can be suppressed.

**Definition 3.11** (Pentagon equation). The *pentagon equation* ensures that the two paths to re-associate  $((a \otimes b) \otimes c) \otimes d$  to  $a \otimes (b \otimes (c \otimes d))$  coincide. In terms of F-symbols (suppressing multiplicity indices):

$$\sum_k (F_{a,b,c}^k)_e^l (F_{a,k,d}^p)_l^m (F_{b,c,d}^p)_k^n = (F_{a,b,n}^p)_e^m (F_{e,c,d}^m)_l^n \quad (13)$$

This coherence condition is required for the fusion category to be well-defined.

### 3.2 R-Symbols and Hexagon Equations

**Definition 3.12** (R-symbols). For a braided fusion category, the *braiding isomorphism*  $c_{a,b} : a \otimes b \rightarrow b \otimes a$  provides a natural way to permute tensor factors. For simple objects  $a, b, c$ , the braiding isomorphism is represented by its matrix elements, the *R-symbols*.

**Definition 3.13** (Hexagon equations). The *hexagon equations* are coherence conditions that relate the associator (F-symbols) and the braiding (R-symbols), ensuring consistency between re-associating and braiding operations. The first hexagon equation:

$$c_{a,b \otimes c} \circ (1_a \otimes c_{b,c}) = ((c_{a,b} \otimes 1_c) \circ F_{b,a,c} \circ (1_b \otimes c_{a,c})) \circ F_{a,c,b}^{-1} \quad (14)$$

This equation (and its dual) ensures that braiding past a composite object can be decomposed consistently.

*Reference:* Etingof–Gelaki–Nikshych–Ostrik, *Tensor Categories*, AMS (2015), §8.1–8.2 [EGNO15] [unverified]

## 4 Morphism Spaces and Multiplicities

**Assumptions.**

- (A3.1.3.1) Fusion category  $(\mathcal{C}, \otimes, \mathbf{1})$  over an algebraically closed field  $k$  (Definition 3.1).
- (A3.1.3.2)  $\mathcal{C}$  is semisimple and  $k$ -linear, so all morphism spaces are finite-dimensional  $k$ -vector spaces.

**Definition 4.1** (Morphism space). For any objects  $A, B \in \mathcal{C}$ ,

$$\text{Mor}(A, B) := \text{Hom}_{\mathcal{C}}(A, B) \quad (15)$$

is a finite-dimensional  $k$ -vector space. If  $A, B$  are simple, Schur's lemma implies  $\dim \text{Mor}(A, B) = \delta_{A,B}$ .

*Reference:* Etingof–Gelaki–Nikshych–Ostrik, *Tensor Categories*, AMS (2015), §4.2 [EGNO15] [unverified]

**Definition 4.2** (Fusion multiplicity space). For simple objects  $X_a, X_b, X_c \in \text{Irr}(\mathcal{C})$ , the space

$$\text{Mor}(X_a \otimes X_b, X_c) \quad (16)$$

has dimension  $N_{ab}^c = \dim \text{Mor}(X_a \otimes X_b, X_c) \in \mathbb{Z}_{\geq 0}$ . A *multiplicity basis* is any choice of morphisms

$$f_{ab \rightarrow c}^{(\mu)} : X_a \otimes X_b \rightarrow X_c, \quad \mu = 1, \dots, N_{ab}^c. \quad (17)$$

No canonical choice exists; computations must remain basis-independent.

**Claim 4.3** (Multiplicity-free simplification). *In the multiplicity-free case ( $N_{ab}^c \in \{0, 1\}$ ), each space  $\text{Mor}(X_a \otimes X_b, X_c)$  is either  $\{0\}$  or a one-dimensional  $k$ -line. Basis dependence disappears, and  $f_{ab \rightarrow c}^{(1)}$  can be chosen uniquely up to phase.*

*Remark 4.4.* Duals:  $\text{Mor}(\mathbf{1}, X_a \otimes X_b)$  is canonically dual to  $\text{Mor}(X_a^* \otimes X_b^*, \mathbf{1})$  via rigidity. Normalisation choices for evaluation/coevaluation maps must be consistent.

*Remark 4.5.* Basis independence is essential for categorical definitions. Fusion-tree bases are admissible for computations (e.g., numerical evaluation of  $F$ -symbols) but must be removed from statements of definitions and theorems.

## 5 Diagrammatic Calculus

**Assumptions.**

- (A3.5.1) Fusion category  $(\mathcal{C}, \otimes, \mathbf{1})$  over  $k = \mathbb{C}$  (Definition 3.1).
- (A3.5.2)  $\mathcal{C}$  is pivotal (left and right duals agree).
- (A3.5.3) All diagrams are read bottom-to-top (source at bottom, target at top).

## 5.1 String Diagrams for Morphisms

String diagrams provide a graphical calculus for computations in monoidal categories. Rather than manipulating algebraic expressions, we draw pictures that encode the same information but make certain properties (like coherence) manifest.

**Definition 5.1** (String diagram). A *string diagram* in a monoidal category represents morphisms graphically according to the following rules:

1. **Objects:** Represented by labelled vertical strings (lines).
2. **Morphisms:** A morphism  $f : A \rightarrow B$  is drawn as a node (box or vertex) with input string  $A$  entering from below and output string  $B$  exiting above.
3. **Composition:** The composite  $g \circ f$  (first  $f$ , then  $g$ ) is drawn by stacking  $g$  above  $f$ .
4. **Tensor product:** The tensor  $f \otimes g$  is drawn by placing  $f$  and  $g$  side-by-side, with  $f$  on the left.
5. **Identity:** The identity morphism  $\text{id}_A : A \rightarrow A$  is a straight vertical line labelled  $A$ .

Figure 1: Basic string diagram elements: identity, morphism, composition, and tensor product.

**Convention 5.2** (Reading order). Throughout this paper, string diagrams are read **bottom-to-top** (inputs at bottom, outputs at top) and tensor factors are ordered **left-to-right**. This follows the categorical convention where composition  $g \circ f$  means “first  $f$ , then  $g$ ”.

For fusion categories, strings are labelled by simple objects  $X_i \in \text{Irr}(\mathcal{C})$ .

*Remark 5.3* (Interchange law). The string diagram calculus automatically encodes the *interchange law*: for composable morphisms  $f_1 : A_1 \rightarrow B_1$ ,  $g_1 : B_1 \rightarrow C_1$ ,  $f_2 : A_2 \rightarrow B_2$ ,  $g_2 : B_2 \rightarrow C_2$ ,

$$(g_1 \otimes g_2) \circ (f_1 \otimes f_2) = (g_1 \circ f_1) \otimes (g_2 \circ f_2). \quad (18)$$

Diagrammatically, this is manifest: both sides describe the same picture of  $f_1, f_2$  below and  $g_1, g_2$  above.

*Reference:* Selinger, *A survey of graphical languages for monoidal categories*, in *New Structures for Physics*, Springer (2011), §4 [unverified]

## 5.2 Isotopy and Pivotal Structure

**Definition 5.4** (Isotopy invariance). String diagrams satisfy *isotopy invariance*: continuously deforming a diagram without crossing strings or moving nodes past each other yields the same morphism. This is a consequence of the coherence theorem for monoidal categories.

**Definition 5.5** (Pivotal category). A *pivotal structure* on a rigid monoidal category provides:

1. A natural isomorphism  $X \cong X^{**}$  (double dual) for each object  $X$ .

2. Consistency between left and right duals.

In a pivotal fusion category, upward and downward strands are related by duality:

- Upward-oriented strand labelled  $X$ : the object  $X$ .
- Downward-oriented strand labelled  $X$ : the dual object  $X^*$ .

Figure 2: In pivotal categories, strand orientation distinguishes  $X$  from  $X^*$ .

*Consequence 5.6.* Pivotal structure allows “bending” strings (cups and caps) without ambiguity, enabling the diagrammatic trace and quantum dimensions (Definition 3.4).

*Reference:* Etingof–Gelaki–Nikshych–Ostrik, *Tensor Categories*, AMS (2015), §4.7 [EGNO15] [unverified]

### 5.3 Evaluation, Coevaluation, and Quantum Dimensions

**Definition 5.7** (Evaluation and coevaluation). For a simple object  $X_i$  with dual  $X_i^*$ :

- **Coevaluation (cup):**  $\text{coev}_i : \mathbf{1} \rightarrow X_i \otimes X_i^*$
- **Evaluation (cap):**  $\text{ev}_i : X_i^* \otimes X_i \rightarrow \mathbf{1}$

These satisfy the *zigzag identities* (rigidity axioms):

$$(\text{ev}_i \otimes \text{id}_{X_i}) \circ (\text{id}_{X_i^*} \otimes \text{coev}_i) = \text{id}_{X_i} \quad (19)$$

$$(\text{id}_{X_i^*} \otimes \text{ev}_i) \circ (\text{coev}_i \otimes \text{id}_{X_i}) = \text{id}_{X_i^*} \quad (20)$$

Figure 3: Coevaluation (cup) and evaluation (cap) morphisms.

Figure 4: The zigzag identity: a bent string straightens to the identity.

**Definition 5.8** (Quantum dimension via loop). The quantum dimension  $d_X$  of a simple object  $X$  equals the value of a closed loop:

$$d_X = \text{ev}_X \circ \text{coev}_X = \bigcirc X \quad (21)$$

Diagrammatically, closing a string labelled  $X$  into a loop evaluates to the scalar  $d_X \in k$ .

A diagram of a closed loop with a small gap at the bottom right, containing the label  $X$  to its right.

Figure 5: A closed loop evaluates to the quantum dimension.

#### 5.4 F-Moves and R-Moves Diagrammatically

**Definition 5.9** (F-move). The *F-move* is the graphical representation of the associator. For simple objects  $a, b, c, d$  with intermediate channels  $e, f$ :

A diagram showing the graphical representation of the associator. On the left, there is a trivalent vertex with three strands entering from below, labeled  $a, b, c$ , and one strand exiting at the top labeled  $d$ . This is followed by an equals sign. To the right of the equals sign is a sum symbol ( $\sum$ ) with  $f$  as the index. Below the sum symbol is another trivalent vertex with three strands entering from below, labeled  $a, b, c$ , and one strand exiting at the top labeled  $f$ . This is followed by a factor  $(F_{abc}^d)_e^f$ .

The F-symbol  $(F_{abc}^d)_e^f$  (with multiplicity indices suppressed) gives the change-of-basis coefficient.

**Definition 5.10** (R-move). For a braided category, the *R-move* (braiding) exchanges two adjacent strands:

A diagram showing the graphical representation of the R-move. On the left, there is a crossing of two strands labeled  $a$  and  $b$ . This is followed by an equals sign. To the right of the equals sign is a factor  $R_{ab}^c$  followed by a vertical bar with two strands labeled  $a$  and  $b$  passing through it.

where the crossing indicates which strand passes over (the R-symbol depends on total charge  $c \in a \otimes b$ ).

*Remark 5.11* (Pentagon and hexagon identities). The F-symbols must satisfy the *pentagon identity*: five ways to re-associate  $(a \otimes b) \otimes c \otimes d$  form a commuting pentagon. For braided categories, the *hexagon identities* relate F-moves and R-moves, ensuring consistency of braiding with associativity.

#### 5.5 Normalisation Choices

**Convention 5.12** (Normalisation). We adopt the following normalisation conventions throughout this paper:

1. **Trivalent vertices:** Fusion vertices  $v_{ab}^{c,\mu} : a \otimes b \rightarrow c$  (with multiplicity index  $\mu$ ) are normalised so that

$$\sum_{\mu} (v_{ab}^{c,\mu})^\dagger v_{ab}^{c,\mu} = \text{id}_{(a \otimes b) \rightarrow c} \quad (24)$$

2. **Quantum dimensions:**  $d_1 = 1$  (vacuum has unit dimension).

3. **Closed loops:** A closed loop labelled  $X_i$  evaluates to  $d_i$ :

$$\bigcirc X_i = d_i \quad (25)$$

4. **F-symbols:** For unitary fusion categories, F-symbols are unitary:

$$\sum_f (F_{abc}^d)_e^f \overline{(F_{abc}^d)_{e'}^f} = \delta_{e,e'} \quad (26)$$

5. **R-symbols:** For unitary braided categories, R-symbols are unitary:

$$(R_{ab}^c)^\dagger R_{ab}^c = 1 \quad (27)$$

*Remark 5.13.* These conventions are compatible with TensorCategories.jl defaults. Any discrepancies with specific literature sources will be documented case-by-case in the relevant sections.

## 5.6 Algebraic vs Diagrammatic Correspondence

**Claim 5.14** (Equivalence of calculi). *The diagrammatic calculus is equivalent to algebraic definitions:*

Algebraic	Diagrammatic
Morphism $f : A \rightarrow B$	Box with $A$ below, $B$ above
Composition $g \circ f$	Vertical stacking
Tensor $f \otimes g$	Horizontal juxtaposition
Associator $\alpha_{a,b,c}$	$F$ -move
Braiding $c_{a,b}$	$R$ -move (crossing)
Dual $X^*$	Reversed strand direction
coev : $\mathbf{1} \rightarrow X \otimes X^*$	Cup (U-shape)
ev : $X^* \otimes X \rightarrow \mathbf{1}$	Cap (inverted U)
Trace $\text{Tr}(f)$	Close strand into loop

*Remark 5.15.* The diagrammatic calculus is more than mere notation: Mac Lane's coherence theorem ensures that any two ways of re-associating yield the same morphism when expressed via F-moves. This makes the graphical calculus a rigorous computational tool.

*Reference:* Etingof–Gelaki–Nikshych–Ostrik, *Tensor Categories*, AMS (2015), Ch. 2 and Ch. 4 [EGNO15] [unverified]

## 6 Fusion Tree Basis

### Assumptions.

(A3.1.6.1) Fusion category  $(\mathcal{C}, \otimes, \mathbf{1})$  over  $k = \mathbb{C}$  (Definition 3.1).

(A3.1.6.2) Simple objects  $\{X_0, X_1, \dots, X_{d-1}\}$  with  $X_0 = \mathbf{1}$  (skeletal convention, Definition 3.6).

(A3.1.6.3) Fusion multiplicities  $N_{ab}^c = \dim \text{Mor}(X_a \otimes X_b, X_c)$  (Definition 4.2).

### 6.1 Fusion Trees as Diagrams

**Definition 6.1** (Binary fusion tree). A *binary fusion tree* with  $n$  external legs (leaves) labelled by simple objects  $a_1, \dots, a_n$  and root labelled by  $c$  is a planar binary tree where:

1. Each leaf carries a label  $a_i \in \text{Irr}(\mathcal{C})$ .
2. Each internal edge carries an *intermediate channel* label  $e \in \text{Irr}(\mathcal{C})$ .

3. Each trivalent vertex with incoming labels  $x, y$  and outgoing label  $z$  satisfies  $N_{xy}^z \geq 1$  (the fusion is allowed).
4. If  $N_{xy}^z > 1$ , the vertex additionally carries a *multiplicity index*  $\mu \in \{1, \dots, N_{xy}^z\}$ .
5. The root edge carries the total charge  $c$ .

**Example 6.2** (Three-anyon fusion tree). For three anyons  $a_1, a_2, a_3$  fusing to total charge  $c$ , the *left-associated* fusion tree corresponds to  $((a_1 \otimes a_2) \otimes a_3) \rightarrow c$ :

The intermediate channel  $e$  ranges over all simple objects with  $N_{a_1 a_2}^e \geq 1$  and  $N_{e a_3}^c \geq 1$ .

## 6.2 Fusion Trees as Basis Vectors

**Proposition 6.3** (Fusion tree basis). *The morphism space  $\text{Mor}(a_1 \otimes \dots \otimes a_n, c)$  has a basis indexed by fusion trees with leaves  $a_1, \dots, a_n$  and root  $c$ . Specifically, for a fixed tree topology  $T$  (e.g., left-associated), the basis vectors are indexed by:*

1. All valid assignments of intermediate channel labels to internal edges.
2. All valid assignments of multiplicity indices to vertices.

The dimension is

$$\dim \text{Mor}(a_1 \otimes \dots \otimes a_n, c) = \sum_{\text{intermediate channels}} \prod_{\text{vertices } v} N_{x_v y_v}^{z_v} \quad (28)$$

where the sum runs over all valid channel assignments and the product over all trivalent vertices.

**Example 6.4** (Dimension of  $\text{Mor}(a \otimes b \otimes c, d)$ ). Using left-association:

$$\dim \text{Mor}(a \otimes b \otimes c, d) = \sum_{e \in \text{Irr}(\mathcal{C})} N_{ab}^e N_{ec}^d. \quad (29)$$

This equals  $\sum_f N_{bc}^f N_{af}^d$  (right-association) by associativity of the Grothendieck ring.

## 6.3 Change of Basis: F-Moves

**Definition 6.5** (F-move as basis change). The *F-move* relates fusion tree bases corresponding to different association orders. For four anyons  $a, b, c, d$ , the F-symbol  $(F_{abc}^d)_e^f$  (suppressing multiplicity indices) gives the overlap between:

- Left-associated basis:  $|((a \otimes b) \otimes c) \rightarrow d; e\rangle$  with intermediate channel  $e$  in  $(a \otimes b)$ .
- Right-associated basis:  $|(a \otimes (b \otimes c)) \rightarrow d; f\rangle$  with intermediate channel  $f$  in  $(b \otimes c)$ .

The change of basis is:

$$|(ab)c \rightarrow d; e\rangle = \sum_f (F_{abc}^d)_e^f |a(bc) \rightarrow d; f\rangle. \quad (30)$$

*Remark 6.6* (Pentagon as consistency). The pentagon equation (Definition 3.11) ensures that any sequence of F-moves relating two tree topologies yields the same result, regardless of the path taken through intermediate topologies. This is the defining coherence condition for monoidal categories.

## 6.4 Basis Independence

**Convention 6.7** (Basis-independent formulations). Physical quantities and categorical definitions should not depend on:

1. The choice of tree topology (left-associated, right-associated, or other).
2. The choice of multiplicity basis vectors  $f_{ab \rightarrow c}^{(\mu)}$ .
3. Overall phase conventions for basis morphisms.

Fusion tree bases are a *computational tool*, not part of the categorical structure.

*Remark 6.8* (When bases are necessary). Explicit bases are required for:

- Numerical computation of matrix elements (Section ??).
- Defining Hamiltonians in terms of F-symbols.
- Interface with TensorCategories.jl and similar software.

In such cases, one must verify that final results are basis-independent, or explicitly state which conventions are used.

*Reference:* Kitaev, *Anyons in an exactly solved model and beyond*, Ann. Phys. 321 (2006), Appendix E [Kit06] [unverified]

## 7 Examples of Fusion Categories

This section enumerates concrete fusion categories used in mobile anyon models. Each example specifies fusion rules, F-symbols, R-symbols (if braided), and the simple object count (rank).

### Assumptions.

(A3.1.8.1) Fusion categories listed here are semisimple and rigid.

(A3.1.8.2) Numerical F/R-symbols are computed via standard references (Kitaev, Rowell).

### 7.1 Fibonacci Category (Multiplicity-Free)

**Category:**  $\mathcal{C}_{\text{Fib}}$

**Rank:**  $d = 2$

**Simple objects:**  $\mathbf{1} = X_0, \tau = X_1$

#### 7.1.1 Fusion Rules

$\otimes$	$\mathbf{1}$	$\tau$
$\mathbf{1}$	$\mathbf{1}$	$\tau$
$\tau$	$\tau$	$\mathbf{1} \oplus \tau$

**Multiplicities:**  $N_{\tau\tau}^{\mathbf{1}} = N_{\tau\tau}^{\tau} = 1$  (multiplicity-free).

#### 7.1.2 Quantum Dimensions

- $d_{\mathbf{1}} = 1$
- $d_{\tau} = \phi = \frac{1+\sqrt{5}}{2}$  (golden ratio)

### 7.1.3 F-Symbols (Associator)

For the only nontrivial fusion channel  $\tau \otimes \tau \rightarrow \mathbf{1} \oplus \tau$ :

$$F_{\tau,\tau,\tau}^{\tau} = \begin{pmatrix} \phi^{-1} & \phi^{-1/2} \\ \phi^{-1/2} & -\phi^{-1} \end{pmatrix} \quad (31)$$

where rows/columns are indexed by the intermediate fusion channel  $e \in \{\mathbf{1}, \tau\}$ , and the matrix connects the two fusion orders:  $(\tau \otimes \tau) \otimes \tau$  vs.  $\tau \otimes (\tau \otimes \tau)$ . This matrix is unitary:  $F^\dagger F = I$ .

**Numerical values:**  $\phi^{-1} = \phi - 1 \approx 0.6180$ ,  $\phi^{-1/2} \approx 0.7861$  [Kit06] [verified]

### 7.1.4 R-Symbols (Braiding)

For the *braided* Fibonacci category (adding R-symbols to the fusion category):

$$R_{\tau,\tau}^{\mathbf{1}} = e^{4\pi i/5}, \quad R_{\tau,\tau}^{\tau} = e^{-3\pi i/5} \quad (32)$$

The topological spin (twist) of  $\tau$  is  $\theta_\tau = e^{4\pi i/5}$ , corresponding to conformal weight  $h_\tau = 2/5$ . [verified]

## 7.2 Ising Category (Multiplicity-Free)

**Category:**  $\mathcal{C}_{\text{Ising}}$

**Rank:**  $d = 3$

**Simple objects:**  $\mathbf{1} = X_0$ ,  $\sigma = X_1$ ,  $\psi = X_2$

### 7.2.1 Fusion Rules

$\otimes$	$\mathbf{1}$	$\sigma$	$\psi$
$\mathbf{1}$	$\mathbf{1}$	$\sigma$	$\psi$
$\sigma$	$\sigma$	$\mathbf{1} \oplus \psi$	$\sigma$
$\psi$	$\psi$	$\sigma$	$\mathbf{1}$

**Multiplicities:** All fusion coefficients are 0 or 1 (multiplicity-free).

### 7.2.2 Quantum Dimensions

- $d_{\mathbf{1}} = 1$
- $d_\sigma = \sqrt{2}$
- $d_\psi = 1$

### 7.2.3 F-Symbols

Non-trivial associators exist for  $\sigma \otimes \sigma \rightarrow \mathbf{1} \oplus \psi$ :

$$F_{\sigma,\sigma,\sigma}^{\sigma} = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix} \quad (33)$$

This is the Hadamard matrix, which is unitary. [verified]

### 7.2.4 R-Symbols

For braided (modular) Ising category:

$$R_{\sigma,\sigma}^{\mathbf{1}} = e^{i\pi/8}, \quad R_{\sigma,\sigma}^{\psi} = e^{-3i\pi/8} \quad (34)$$

The topological spin of  $\sigma$  is  $\theta_\sigma = e^{i\pi/8}$ . [verified]

### 7.3 $\mathbb{Z}_N$ Categories (Pointed)

**Category:**  $\mathcal{C}_{\mathbb{Z}_N}$

**Rank:**  $d = N$

**Simple objects:**  $X_0, X_1, \dots, X_{N-1}$  (cyclic group)

#### 7.3.1 Fusion Rules

$$X_a \otimes X_b = X_{(a+b) \bmod N} \quad (35)$$

**Multiplicities:** All  $N_{ab}^c = 0$  or  $1$  (multiplicity-free for standard abelian fusion).

#### 7.3.2 Quantum Dimensions

$d_{X_a} = 1$  for all  $a$ . (For abelian/group-like categories, all objects are invertible and hence have quantum dimension 1; see EGNO §8.4 [EGNO15].)

#### 7.3.3 F-Symbols

For abelian (group-like) fusion, all nontrivial associators are trivial:

$$F_{a,b,c}^e = 1 \quad (36)$$

#### 7.3.4 R-Symbols

Braiding given by a 2-cocycle  $\sigma(a, b) \in U(1)$ :

$$R_{a,b}^{a+b} = \sigma(a, b) \quad (37)$$

**Example 7.1** ( $\mathbb{Z}_2$  with fermionic statistics).

$$R_{f,f}^1 = -1 \quad (38)$$

### 7.4 sVec Category (Fermionic)

**Category:**  $\mathcal{C}_{s\text{Vec}}$

**Rank:**  $d = 2$

**Simple objects:**  $\mathbf{1} = X_0$  (boson),  $\psi = X_1$  (fermion)

#### 7.4.1 Fusion Rules

$\otimes$	$\mathbf{1}$	$\psi$
$\mathbf{1}$	$\mathbf{1}$	$\psi$
$\psi$	$\psi$	$\mathbf{1}$

**Multiplicities:** Multiplicity-free ( $N_{\psi\psi}^{\mathbf{1}} = 1$ ).

#### 7.4.2 Quantum Dimensions

- $d_{\mathbf{1}} = 1$

- $d_{\psi} = 1$  (fermionic dimension)

#### 7.4.3 F-Symbols

For fermionic fusion (super-case), the associator has an extra sign:

$$F_{\psi,\psi,\psi}^{\mathbf{1}} = 1 \quad (\text{standard}) \quad (39)$$

But crossing rules differ due to Fermi statistics.

#### 7.4.4 R-Symbols

$$R_{\psi,\psi}^1 = e^{i\pi} = -1 \quad (40)$$

(fermionic exchange is anticommuting; eigenvalue is  $-1$ ).

### 7.5 Categories with Multiplicities

Most physically relevant fusion categories are multiplicity-free ( $N_{ab}^c \in \{0, 1\}$ ), but multiplicities arise in important examples.

#### 7.5.1 $SU(2)_k$ for $k \geq 3$

**Category:**  $\mathcal{C}_{SU(2)_k}$  (level- $k$  truncation of  $SU(2)$  representations)

**Rank:**  $d = k + 1$

**Simple objects:**  $V_0, V_1, \dots, V_k$  (spin- $j/2$  representations with  $j = 0, 1, \dots, k$ )

**Fusion rules:** Truncated Clebsch–Gordan:

$$V_a \otimes V_b = \bigoplus_{c=|a-b|}^{\min(a+b, 2k-a-b)} V_c \quad (41)$$

where the sum runs in steps of 2.

**Multiplicities:** For  $k \geq 3$ , we have  $N_{ab}^c > 1$  in some cases. For instance, in  $SU(2)_4$ :

$$V_2 \otimes V_2 = V_0 \oplus V_2 \oplus V_4 \quad (42)$$

is multiplicity-free, but higher levels exhibit multiplicities.

*Remark 7.2* (Other multiplicity examples). Categories with multiplicities include:

- Haagerup categories  $\mathcal{H}_1, \mathcal{H}_2, \mathcal{H}_3$  (exotic fusion categories)
- Tambara–Yamagami categories for non-abelian groups
- Representation categories of quantum groups at roots of unity

The general framework developed in this paper handles multiplicities via multiplicity indices (Remark 3.10).

### 7.6 Summary Table

Category	Rank	Mult-Free?	Braided?	Modular?	Status
Fibonacci	2	✓	✓	✓	Implemented
Ising	3	✓	✓	✓	Implemented

Table 1: Summary of fusion category examples.

*Remark 7.3. Unverified:* All F/R-symbol values marked [unverified] pending HITL review against literature.

*Remark 7.4. Not exhaustive:* Other fusion categories (e.g., Haagerup,  $SU(2)_k$ , Tambara–Yamagami) can be added as needed. Note: Potts models and Virasoro algebras are related CFT structures but are not themselves fusion categories.

## 8 Temperley–Lieb Categories

**Assumptions.**

- (A1) Loop fugacity  $n = q + q^{-1}$  for quantum parameter  $q$ .
- (A2) At roots of unity  $q = e^{i\pi/p}$ , the category truncates to finitely many simples.
- (A3) Standard normalisation: loop evaluates to  $\delta = -[2]_q$ .

### 8.1 Overview

The *Temperley–Lieb (TL) category* is a fundamental example connecting fusion categories to statistical mechanics, loop models, and conformal field theory. TL categories provide:

1. A continuous interpolation between solvable models via the loop fugacity parameter.
2. Concrete realisations of Fibonacci ( $q = e^{i\pi/5}$ ) and Ising ( $q = e^{i\pi/4}$ ) anyons.
3. Direct connection to critical phenomena and CFT via the central charge formula.

### 8.2 Loop Fugacity Parametrisation

The TL category is parametrised by the *loop fugacity*  $n$ , related to the quantum parameter  $q$  by:

$$n = q + q^{-1} = 2 \cos \theta, \quad q = e^{i\theta}. \quad (43)$$

**Example 8.1** (Key values of loop fugacity).

$p$ (for $q = e^{i\pi/p}$ )	$n = 2 \cos(\pi/p)$	Physical model
$p = 3$	$n = 1$	Percolation
$p = 4$	$n = \sqrt{2}$	Ising ( $\sigma$ -anyon)
$p = 5$	$n = \phi = \frac{1+\sqrt{5}}{2}$	Fibonacci ( $\tau$ -anyon)
$p = 6$	$n = \sqrt{3}$	3-state Potts
$p \rightarrow \infty$	$n \rightarrow 2$	Free fermion

At roots of unity, the representation theory truncates, yielding *modular tensor categories* with finitely many simple objects.

### 8.3 Quantum Numbers

**Definition 8.2** (Quantum integer). For  $q = e^{i\pi/p}$ , the *quantum integer* is:

$$[n]_q = \frac{q^n - q^{-n}}{q - q^{-1}} = \frac{\sin(n\pi/p)}{\sin(\pi/p)}. \quad (44)$$

**Definition 8.3** (Quantum factorial and binomial). The *quantum factorial* and *quantum binomial* are:

$$[n]_q! = [1]_q [2]_q \cdots [n]_q, \quad \binom{n}{k}_q = \frac{[n]_q!}{[k]_q! [n-k]_q!}. \quad (45)$$

*Remark 8.4.* At roots of unity,  $[p-1]_q = 0$ , causing the truncation of the representation theory.

## 8.4 Simple Objects and Fusion Rules

At generic  $q$ , the TL category has infinitely many simple objects labelled by half-integers  $j \in \{0, \frac{1}{2}, 1, \frac{3}{2}, \dots\}$ , corresponding to spins in the representation theory of  $U_q(\mathfrak{sl}_2)$ .

At roots of unity  $q = e^{i\pi/p}$ , the category *truncates* to:

$$j \in \left\{ 0, \frac{1}{2}, 1, \dots, \frac{p-2}{2} \right\}. \quad (46)$$

**Definition 8.5** (TL fusion rules). The fusion rules are the  $SU(2)_q$  rules with truncation:

$$j_1 \otimes j_2 = \bigoplus_{j=|j_1-j_2|}^{\min(j_1+j_2, p-2-j_1-j_2)} j. \quad (47)$$

## 8.5 Connection to Key Examples

**Example 8.6** (Fibonacci anyons,  $p = 5$ ). Two simple objects  $\{\mathbf{1}, \tau\}$  with  $\tau \otimes \tau = \mathbf{1} \oplus \tau$ .

**Example 8.7** (Ising anyons,  $p = 4$ ). Three simple objects  $\{\mathbf{1}, \sigma, \psi\}$  with:

$$\sigma \otimes \sigma = \mathbf{1} \oplus \psi, \quad (48)$$

$$\psi \otimes \psi = \mathbf{1}, \quad (49)$$

$$\sigma \otimes \psi = \sigma. \quad (50)$$

## 8.6 Critical Behaviour

**Theorem 8.8** (Central charge). At  $q = e^{i\pi/p}$ , the TL algebra describes critical points with central charge:

$$c = 1 - \frac{6(p-1)^2}{p}. \quad (51)$$

This connects TL categories to minimal model CFTs  $\mathcal{M}(p, p-1)$ .

# 9 Fock Space Perspective (First Quantisation)

## Assumptions.

(A3.2.1) First-quantised formalism only (no  $a^\dagger, a$ ).

(A3.2.2) Fock space is a direct sum of fixed-number sectors.

## 9.1 Standard Fock Space

**Definition 9.1** (Fock space). The *Fock space*  $\mathcal{F}$  is the direct sum of  $N$ -particle Hilbert spaces  $\mathcal{H}_N$  for all possible particle numbers  $N \geq 0$ :

$$\mathcal{F} = \bigoplus_{N=0}^{\infty} \mathcal{H}_N = \mathcal{H}_0 \oplus \mathcal{H}_1 \oplus \mathcal{H}_2 \oplus \dots \quad (52)$$

where  $\mathcal{H}_0 \cong \mathbb{C}$  is the vacuum sector spanned by the vacuum state  $|\Omega\rangle$ .

*Remark 9.2.* In this first-quantised approach, a state  $|\Psi\rangle \in \mathcal{F}$  is a sequence of wavefunctions (or categorical states)  $|\Psi\rangle = (\psi_0, \psi_1, \psi_2, \dots)$ , where  $\psi_N \in \mathcal{H}_N$  is the projection of the state onto the  $N$ -particle sector.

**Constraint 9.3.** We strictly avoid the use of second-quantised creation/annihilation operators ( $a_i^\dagger, a_i$ ) as fundamental building blocks. While convenient for bosons/fermions, they obscure the categorical data (braiding, fusion) essential for anyons.

## 9.2 Direct Sum as “OR Quantifier”

The direct sum ( $\oplus$ ) operation represents a logical “OR” or superposition of different particle number sectors.

- A state in  $\mathcal{H}_1 \oplus \mathcal{H}_2$  describes a system that is in a superposition of having 1 particle **OR** 2 particles.
- This contrasts with the tensor product (see §9.3).

This perspective highlights that the total Hilbert space allows for quantum fluctuations in particle number, even if dynamics (Hamiltonian) conserve it.

## 9.3 Tensor Product as “AND Quantifier”

The tensor product ( $\otimes$ ) operation represents a logical “AND” or composition of subsystems.

- Within a fixed  $N$ -particle sector  $\mathcal{H}_N$ , the structure involves tensor products of single-particle spaces (or local site spaces):

$$\mathcal{H}_N \sim \mathcal{H}_{\text{loc}} \otimes \cdots \otimes \mathcal{H}_{\text{loc}} \quad (\text{schematically}) \quad (53)$$

- A state  $|\phi\rangle \otimes |\chi\rangle$  describes a system where part A is in state  $\phi$  **AND** part B is in state  $\chi$ .

*Remark 9.4* (Anyonic nuance). For anyons,  $\mathcal{H}_N$  is not a simple tensor product of single-particle spaces due to fusion constraints (fusion spaces are not product spaces). However, the *ambient* space in which  $\mathcal{H}_N$  is embedded (before fusion constraints) often has a tensor product structure (e.g., sites on a lattice).

## 9.4 First-Quantised Operators

**Definition 9.5** (Operator on Fock space). An operator  $\hat{O} : \mathcal{F} \rightarrow \mathcal{F}$  is defined by its action on each sector  $\mathcal{H}_N$  and maps between sectors. It can be represented as a matrix of operators  $\hat{O}_{MN} : \mathcal{H}_N \rightarrow \mathcal{H}_M$ .

**Definition 9.6** (Number-conserving operator). An operator  $\hat{H}$  is *number-conserving* if it maps each sector  $\mathcal{H}_N$  to itself ( $\hat{H}_{MN} = 0$  for  $M \neq N$ ). It decomposes as a direct sum of operators acting on fixed-number sectors:

$$\hat{H} = \bigoplus_{N=0}^{\infty} \hat{H}_N \quad (54)$$

where  $\hat{H}_N : \mathcal{H}_N \rightarrow \mathcal{H}_N$ .

**Example 9.7.** The Hamiltonian for mobile anyons is typically number-conserving (unless studying source terms), so we construct it by defining a sequence of Hamiltonians  $H_N$  for each  $N$ -anyon configuration space.

## 9.5 Summary

Structure	Symbol	Interpretation	Logical Equiv.
Direct Sum	$\oplus$	Superposition of sectors	<b>OR</b>
Tensor Product	$\otimes$	Composition of parts	<b>AND</b>
Fock Space	$\mathcal{F}$	$\bigoplus_N \mathcal{H}_N$	Variable particle number
Operator	$\hat{O}$	$\bigoplus_N \hat{O}_N$ (if conserved)	Collection of $N$ -particle ops

## 10 Quantum Mechanics for Lattice Models

### Assumptions.

(A3.3.1) All Hilbert spaces are finite-dimensional.

(A3.3.2) Hamiltonians are Hermitian.

### 10.1 Hilbert Spaces, States, Observables

We consider a finite-dimensional *Hilbert space*  $\mathcal{H} \cong \mathbb{C}^d$  with inner product  $\langle \cdot | \cdot \rangle$ . A *state* is a unit vector  $|\psi\rangle \in \mathcal{H}$  (defined up to phase), and an *observable* is a Hermitian operator  $A \in \text{End}(\mathcal{H})$  such that  $A = A^\dagger$ . Measurements yield eigenvalues of  $A$  with probabilities given by the Born rule.

### 10.2 Hamiltonians for Lattice Systems

**Definition 10.1** (Hamiltonian). A *Hamiltonian* is a Hermitian operator  $H : \mathcal{H} \rightarrow \mathcal{H}$  representing the total energy of the system (generator of time evolution).

**Definition 10.2** (Local Hamiltonian). A Hamiltonian  $H$  is *local* if it decomposes as a sum of terms  $H = \sum_j h_j$ , where each term  $h_j$  has finite *support* localised near site  $j$ . The *support* of an operator  $A$  on a tensor product space  $\mathcal{H} = \bigotimes_i \mathcal{H}_i$  is the minimal set of sites  $S$  such that  $A$  acts as the identity on all sites  $k \notin S$  (i.e.,  $A$  acts trivially outside  $S$ ,  $A = A_S \otimes \mathbb{I}_{S^c}$ ).

**Definition 10.3** (Nearest-neighbour Hamiltonian). A Hamiltonian is *nearest-neighbour* if each term  $h_j$  acts nontrivially only on sites  $j$  and  $j + 1$ .

### 10.3 Ground States, Spectrum, Partition Function

**Definition 10.4** (Spectrum). The *spectrum* of  $H$  is the set of eigenvalues  $\{E_0, E_1, \dots\}$  ordered so that  $E_0 \leq E_1 \leq \dots$

**Definition 10.5** (Ground state). A *ground state* is an eigenvector of  $H$  with eigenvalue  $E_0$  (the minimum eigenvalue).

**Definition 10.6** (Spectral gap). The *spectral gap* is  $\Delta = E_1 - E_0$ .

**Definition 10.7** (Partition function). The *partition function* at inverse temperature  $\beta$  is

$$Z(\beta) = \text{Tr}\left(e^{-\beta H}\right) = \sum_n e^{-\beta E_n} \quad (55)$$

## 10.4 Tensor Product Structure

**Definition 10.8** (Tensor product of Hilbert spaces). Given Hilbert spaces  $\mathcal{H}_1, \mathcal{H}_2$ , the *tensor product*  $\mathcal{H}_1 \otimes \mathcal{H}_2$  is a Hilbert space with:

- $\dim(\mathcal{H}_1 \otimes \mathcal{H}_2) = \dim(\mathcal{H}_1) \cdot \dim(\mathcal{H}_2)$
- Basis:  $\{|i\rangle \otimes |j\rangle\}$  for bases  $\{|i\rangle\}$  of  $\mathcal{H}_1$  and  $\{|j\rangle\}$  of  $\mathcal{H}_2$

**Definition 10.9** (Multi-site Hilbert space). For  $n$  sites with local Hilbert space  $\mathcal{H}_{\text{loc}}$  of dimension  $d$ , the total Hilbert space is

$$\mathcal{H}_{\text{total}} = \bigotimes_{j=1}^n \mathcal{H}_{\text{loc}} \cong \mathbb{C}^{d^n} \quad (56)$$

*Remark 10.10.* The tensor product represents the “AND quantifier”: a state in  $\mathcal{H}_1 \otimes \mathcal{H}_2$  describes a system where both subsystem 1 AND subsystem 2 exist simultaneously. Cf. §9.

## 10.5 Summary

Concept	Symbol	Definition
Hilbert space	$\mathcal{H}$	Finite-dim complex inner product space
State	$ \psi\rangle$	Nonzero vector in $\mathcal{H}$
Observable	$A$	Hermitian operator
Hamiltonian	$H$	Hermitian operator (energy)
Ground state	$ \psi_0\rangle$	Eigenvector with minimal eigenvalue
Partition function	$Z(\beta)$	$\text{Tr}(e^{-\beta H})$
Tensor product	$\otimes$	“AND quantifier” for composite systems

## 11 Lattice Geometry

### Assumptions.

- (A3.4.1) Spatial dimension is 1.
- (A3.4.2) Open boundary conditions (no PBCs).
- (A3.4.3) Finite number of sites.

### 11.1 One-Dimensional Chain

**Definition 11.1** (Lattice). A *lattice*  $\Lambda$  is a finite set of sites. In this work:

$$\Lambda = \{0, 1, 2, \dots, n - 1\} \quad (57)$$

where  $n = |\Lambda|$  is the number of sites.

*Remark 11.2.* We use 0-based indexing for sites to align with physical position  $x_j = \epsilon \cdot j$ .

**Definition 11.3** (Neighbour relation). Sites  $i$  and  $j$  are *neighbours* if  $|i - j| = 1$ . We write  $i \sim j$ .

**Definition 11.4** (Boundary sites). The *boundary* of  $\Lambda$  consists of sites 0 and  $n - 1$ . The *bulk* consists of sites  $\{1, \dots, n - 2\}$ .

## 11.2 Lattice Spacing and Physical Position

**Definition 11.5** (Physical length). The *physical length* of the system is  $L > 0$ .

**Definition 11.6** (Lattice spacing). The *lattice spacing* is

$$\epsilon = \frac{L}{n} \quad (58)$$

**Definition 11.7** (Physical position). The *physical position* of site  $j$  is

$$x_j = \epsilon \cdot j = \frac{L \cdot j}{n} \quad (59)$$

so that  $x_0 = 0$  and  $x_{n-1} = L(1 - 1/n) < L$ .

**Convention 11.8.** Where convenient, we set  $\epsilon = 1$  (equivalently,  $L = n$ ), so that site index equals physical position.

## 11.3 Open Boundary Conditions

**Definition 11.9** (Open boundary conditions). A system has *open boundary conditions* (OBC) if:

1. The lattice is a finite chain with distinct endpoints
2. Site 0 has only one neighbour (site 1)
3. Site  $n - 1$  has only one neighbour (site  $n - 2$ )

*Remark 11.10.* This contrasts with *periodic boundary conditions* (PBC) where site  $n - 1$  is also a neighbour of site 0. We exclude PBCs in this work (Assumption A3.4.2).

*Remark 11.11.* OBC implies:

- No topological ground state degeneracy from nontrivial cycles
- Edge effects may be present
- Total charge is well-defined without ambiguity from winding

## 11.4 Local Hilbert Spaces

**Definition 11.12** (Local Hilbert space). For an anyonic system described by a fusion category  $\mathcal{C}$ , the *local Hilbert space*  $\mathcal{H}_j$  at site  $j$  is identified with the vector space spanned by the simple objects of  $\mathcal{C}$  (viewed as possible particle types at that site):

$$\mathcal{H}_j \cong \bigoplus_{a \in \text{Irr}(\mathcal{C})} \mathbb{C}|a\rangle_j \quad (60)$$

where  $\text{Irr}(\mathcal{C}) = \{\mathbf{1} = X_0, X_1, \dots, X_{d-1}\}$  is the set of isomorphism classes of simple objects. The dimension is  $d_{\text{loc}} = |\text{Irr}(\mathcal{C})|$ , the rank of the category.

*Remark 11.13.* This definition naturally accommodates the hard-core constraint where at most one anyon occupies a site. In this context, the “vacuum” state corresponds to the unit object  $|X_0\rangle_j = |\mathbf{1}\rangle_j$  (no topological charge). For soft-core models allowing multiple anyons per site, the local space would be larger, involving fusion spaces of multiple anyons (see §15).

## 11.5 Summary

Concept	Symbol	Value/Definition
Number of sites	$n$	$ \Lambda $
Site indices	$j$	$0, 1, \dots, n - 1$
Physical length	$L$	System size
Lattice spacing	$\epsilon$	$L/n$
Physical position	$x_j$	$\epsilon \cdot j$
Local Hilbert space	$\mathcal{H}_j$	Space at site $j$
Local dimension	$d_{\text{loc}}$	$\dim(\mathcal{H}_{\text{loc}})$
Total dimension	—	$d^n$

## 11.6 Notation Conventions

Throughout this project:

- Sites are **0-indexed**:  $j \in \{0, 1, \dots, n - 1\}$
- Boundary conditions are **open** (OBC)
- Default:  $\epsilon = 1$  unless stated otherwise
- Tensor products are ordered left-to-right:  $\mathcal{H}_0 \otimes \mathcal{H}_1 \otimes \dots \otimes \mathcal{H}_{n-1}$

## Part II

# Hilbert Space for Mobile Anyons

## 12 Classical Configuration Space

### Assumptions.

(A4.1.1) Fusion category  $\mathcal{C}$  with simples  $\{X_0, X_1, \dots, X_{d-1}\}$  where  $X_0 = \mathbf{1}$ .

(A4.1.2) Lattice  $\Lambda = \{0, \dots, n - 1\}$  with OBC.

### 12.1 Anyon Positions

**Definition 12.1** (Configuration). A *configuration* of  $N$  anyons is a tuple

$$\mathbf{j} = (j_1, j_2, \dots, j_N) \in \Lambda^N \quad (61)$$

satisfying  $0 \leq j_1 \leq j_2 \leq \dots \leq j_N \leq n - 1$ .

*Remark 12.2.* The ordering  $j_1 \leq \dots \leq j_N$  reflects indistinguishability up to exchange. Distinct orderings related by permutation represent the same physical configuration.

### 12.2 Anyon Labels

**Definition 12.3** (Labelled configuration). A *labelled configuration* is a pair  $(\mathbf{j}, \mathbf{k})$  where:

- $\mathbf{j} = (j_1, \dots, j_N)$  is a configuration
- $\mathbf{k} = (k_1, \dots, k_N)$  with  $k_m \in \{1, \dots, d - 1\}$  labels the anyon type at site  $j_m$

**Convention 12.4.** Label 0 denotes vacuum (no anyon). Labels  $1, \dots, d - 1$  denote the nontrivial simple objects  $X_1, \dots, X_{d-1}$ .

### 12.3 Configuration Space

**Definition 12.5** ( $N$ -anyon configuration space).

$$\text{Conf}_N = \{(\mathbf{j}, \mathbf{k}) : \mathbf{j} \in \Lambda^N \text{ ordered}, k_m \in \{1, \dots, d-1\}\} \quad (62)$$

**Definition 12.6** (Hard-core configuration space). With hard-core constraint:

$$\text{Conf}_N^{\text{HC}} = \{(\mathbf{j}, \mathbf{k}) \in \text{Conf}_N : j_1 < j_2 < \dots < j_N\} \quad (63)$$

**Claim 12.7.**  $|\text{Conf}_N^{\text{HC}}| = \binom{n}{N}(d-1)^N$ .

### 12.4 Mixed Character

*Remark 12.8.* Configurations have mixed identical/distinguishable character:

- Anyons with *same label*  $k_i = k_j$  are identical
- Anyons with *different labels*  $k_i \neq k_j$  are distinguishable

This is handled by the morphism space structure in §13.

## 13 Hilbert Space for Mobile Anyons

### 13.1 Notation: Disambiguation of Symbol $N$

**Convention 13.1** (Disambiguation of  $N$ ). The symbol  $N$  is overloaded in this section with three distinct meanings. Context distinguishes them:

Context	Meaning	Example
Subscript: $\mathcal{H}_N, \mathcal{H}_N^{(c)}$	Particle number sector	$\mathcal{H}_3 =$ sector with 3 anyons
Superscript: $N_{ab}^c$	Fusion multiplicity	$N_{12}^0 \in \{0, 1\}$ in Fibonacci
Variable: $N \in \{1, \dots, n\}$	Particle number (variable)	$\bigoplus_{N=0}^n$

All three use the same letter but are syntactically distinct. Avoid using plain  $N$  alone; always include subscript/superscript or context.

#### Assumptions.

(A4.2.1) Fusion category  $\mathcal{C}$  with unit **1** and simples  $X_0 = \mathbf{1}, X_1, \dots, X_{d-1}$ .

(A4.2.2)  $n$  lattice sites, OBC.

### 13.2 Morphism Spaces

**Definition 13.2** (Morphism space). For objects  $A, B \in \mathcal{C}$ :

$$\text{Mor}(A, B) = \text{Hom}_{\mathcal{C}}(A, B) \quad (64)$$

This is a finite-dimensional complex vector space with  $\dim \text{Mor}(A, B) = \delta_{A,B}$  for simple  $A, B$  (in the multiplicity-free case).

*Remark 13.3.* With multiplicity:  $\dim \text{Mor}(X_a \otimes X_b, X_c) = N_{ab}^c$ .

### 13.3 $N$ -Anyons Sector with Definite Charge

**Definition 13.4** (Site occupation). For a labelled configuration  $(\mathbf{j}, \mathbf{k})$  on  $n$  sites, define the *site label*  $s_m \in \{0, 1, \dots, d - 1\}$  for each site  $m \in \{0, \dots, n - 1\}$ :

$$s_m = \begin{cases} k_i & \text{if } j_i = m \text{ for some } i \in \{1, \dots, N\} \\ 0 & \text{otherwise (site unoccupied, i.e., vacuum } \mathbf{1}\text{)} \end{cases} \quad (65)$$

**Definition 13.5** (Object for configuration). The *tensor product object* for a labelled configuration  $(\mathbf{j}, \mathbf{k})$  is:

$$\mathcal{O}(\mathbf{j}, \mathbf{k}) = X_{s_0} \otimes X_{s_1} \otimes \cdots \otimes X_{s_{n-1}} \quad (66)$$

This is a tensor product over all  $n$  sites, with  $X_0 = \mathbf{1}$  (vacuum) at unoccupied sites.

*Remark 13.6* (Tensor product ordering convention). The tensor product is ordered by *site index*  $m = 0, 1, \dots, n - 1$  (left-to-right on the lattice). This ordering is a convention: any fixed ordering is equivalent up to associators. The fusion tree formalism (§13.6) provides an explicit way to handle the associativity ambiguity by specifying a parenthesisation. Different parenthesisations (different fusion trees) give orthogonal basis vectors related by F-moves.

**Definition 13.7** ( $N$ -anyon space, definite charge). The space of  $N$  anyons with total charge  $c$ :

$$\mathcal{H}_N^{(c)} = \bigoplus_{(\mathbf{j}, \mathbf{k}) \in \text{Conf}_N} \text{Mor}(X_c, \mathcal{O}(\mathbf{j}, \mathbf{k})) \quad (67)$$

*Remark 13.8.* A state  $|\psi\rangle \in \mathcal{H}_N^{(c)}$  is a superposition over configurations, with amplitudes in the appropriate morphism spaces. The morphism  $\text{Mor}(X_c, \mathcal{O}(\mathbf{j}, \mathbf{k}))$  describes how anyons at the specified positions fuse to total charge  $X_c$ .

### 13.4 $N$ -Anyons Sector with Indefinite Charge

**Definition 13.9** ( $N$ -anyon space, indefinite charge).

$$\mathcal{H}_N = \bigoplus_{c=0}^{d-1} \mathcal{H}_N^{(c)} \quad (68)$$

*Remark 13.10.* Direct sum = “OR quantifier”: the system has charge  $X_0$  OR charge  $X_1$  OR ...

### 13.5 Total Hilbert Space

**Definition 13.11** (Total Hilbert space).

$$\mathcal{H} = \bigoplus_{N=0}^n \mathcal{H}_N \quad (69)$$

where  $\mathcal{H}_0 = \mathbb{C}$  (vacuum sector).

*Remark 13.12.* Direct sum over  $N$  = “OR quantifier” for particle number. This is the first-quantised Fock space structure (cf. §9).

## 13.6 Fusion Trees

Fusion trees provide an equivalent and explicit way to handle the tensor product ordering ambiguity. Rather than treating  $X_{s_0} \otimes X_{s_1} \otimes \cdots \otimes X_{s_{n-1}}$  as an abstract  $n$ -fold tensor product, a fusion tree specifies a concrete parenthesisation (binary bracketing) that determines which pairs fuse first.

**Definition 13.13** (Fusion tree). A *fusion tree*  $\tau$  for a configuration  $(\mathbf{j}, \mathbf{k})$  with  $N$  anyons is a labelling of internal nodes in a **binary tree** that encodes how the anyons fuse step-by-step to produce a final total charge. Formally:

1. **Leaves:** The  $N$  anyons occupy the leaves, labelled with their types  $X_{k_1}, \dots, X_{k_N}$ .
2. **Internal nodes:** Each internal node is labelled with an intermediate fusion result  $X_e$  (some simple object of  $\mathcal{C}$ ).
3. **Binary structure:** Each internal node has exactly two children (left and right), and the label at that node represents the fusion result: left child  $\otimes$  right child.
4. **Root:** The root node is labelled with the final total charge  $X_c$ .

*Remark 13.14.* The fusion tree is not unique (not canonical) due to associativity of tensor products: different parenthesisations yield different tree structures, all yielding the same tensor product result. For multiplicity-free categories ( $N_{ab}^c \in \{0, 1\}$ ), all choices span the same morphism space  $\text{Mor}(X_c, \mathcal{O}(\mathbf{j}, \mathbf{k}))$ , but individual basis vectors depend on the choice.

**Claim 13.15.** *Different fusion trees  $\tau \neq \tau'$  for the same configuration and charge are orthogonal basis vectors. The transition amplitudes between different tree bases are determined by the F-symbols of the category.*

## 13.7 Explicit Construction

For hard-core anyons, a basis of  $\mathcal{H}_N^{(c)}$  is indexed by:

1. Configuration  $(\mathbf{j}, \mathbf{k}) \in \text{Conf}_N^{\text{HC}}$
2. Fusion tree  $\tau$  from  $\mathcal{O}(\mathbf{j}, \mathbf{k})$  to  $X_c$
3. Multiplicity indices (if  $N_{ab}^c > 1$ )

**Claim 13.16.** *For multiplicity-free categories:*

$$\dim \mathcal{H}_N^{(c)} = \sum_{(\mathbf{j}, \mathbf{k})} \dim \text{Mor}(X_c, \mathcal{O}(\mathbf{j}, \mathbf{k})) \quad (70)$$

## 14 Operators as Morphisms

**Planning ref:** §4.3

**Dependency note:** This section is logically prior to §13. We define operators as abstract categorical morphisms first, then show in §13 how they act on the concrete Hilbert space.

### Assumptions.

(A4.3.1) We work with finite tensor products of simple objects.

(A4.3.2) The fusion category  $\mathcal{C}$  has finitely many simple objects.

## 14.1 Abstract Operator Definition (Category-Level)

**Definition 14.1** (Morphism space operator). An *operator* is an element of a morphism space:

$$\mathcal{O} \in \text{Mor}(A, B) \quad (71)$$

where  $A, B$  are tensor products of simple objects from  $\mathcal{C}$ .

*Remark 14.2.* This is a purely categorical definition, independent of any representation or Hilbert space. Morphisms are abstract; they follow categorical axioms (composition, associativity, identities).

**Definition 14.3** (Operator as morphism sum). The space of all operators in this categorical sense is:

$$\mathfrak{Op}_{\text{cat}} = \bigoplus_{n_A, n_B \in \mathbb{Z}_{\geq 0}} \bigoplus_{\substack{(a_1, \dots, a_{n_A}) \\ a_i \in \{1, \dots, d-1\}}} \bigoplus_{\substack{(b_1, \dots, b_{n_B}) \\ b_j \in \{1, \dots, d-1\}}} \text{Mor}(X_{a_1} \otimes \dots \otimes X_{a_{n_A}}, X_{b_1} \otimes \dots \otimes X_{b_{n_B}}) \quad (72)$$

where the nested direct sums run over:

- $n_A, n_B \in \mathbb{Z}_{\geq 0}$  — number of non-vacuum factors
- Labels  $a_i, b_j \in \{1, \dots, d-1\}$  — indices of simple objects (excluding vacuum  $X_0 = \mathbf{1}$ )

By semisimplicity,  $\text{Mor}(A, B)$  is a finite-dimensional vector space for each choice of  $A, B$ .

*Remark 14.4.* Objects with  $n_A = 0$  are identified with  $\mathbf{1}$  (tensor unit), so  $X_\emptyset = \mathbf{1}$ . This definition is independent of the Hilbert space  $\mathcal{H}$  and does not require it to be defined yet.

## 14.2 Action on Hilbert Space (Concrete Representation)

Once the Hilbert space  $\mathcal{H}$  is defined (Definition 13.11), morphism operators are promoted to linear maps via a representation:

**Definition 14.5** (Representation of operators on  $\mathcal{H}$ ). A *representation* of the morphism space  $\text{Mor}(A, B)$  on the Hilbert space  $\mathcal{H}$  is a linear embedding:

$$\rho : \text{Mor}(A, B) \rightarrow \text{Lin}(\mathcal{H}_A \rightarrow \mathcal{H}_B) \quad (73)$$

where  $\mathcal{H}_A$  denotes the sector of  $\mathcal{H}$  corresponding to object  $A$ , and  $\text{Lin}$  denotes linear maps.

The full operator algebra on  $\mathcal{H}$  is:

$$\text{End}(\mathcal{H}) = \bigoplus_{A, B} \text{Lin}(\mathcal{H}_A \rightarrow \mathcal{H}_B) \quad (74)$$

## 14.3 Particle-Number Conservation (at Category Level)

**Definition 14.6** (Particle-number of object). For an object  $A = X_{a_1} \otimes \dots \otimes X_{a_n}$ , define:

$$N(A) = n \quad (75)$$

(the number of nontrivial factors, excluding vacuum  $\mathbf{1}$ ).

**Definition 14.7** (Particle-conserving morphism). A morphism  $\phi \in \text{Mor}(A, B)$  is *particle-conserving* if:

$$N(A) = N(B) \quad (76)$$

**Definition 14.8** (Particle-changing morphism). A morphism  $\phi \in \text{Mor}(A, B)$  is *particle-changing* if:

$$N(A) \neq N(B) \quad (77)$$

**Example 14.9.** •  $\text{Mor}(X_a \otimes X_b, X_c)$  is particle-annihilating:  $N(A) = 2, N(B) = 1$ .

- $\text{Mor}(X_a, X_b \otimes X_c)$  is particle-creating:  $N(A) = 1, N(B) = 2$ .

## 14.4 Locality

**Definition 14.10** (Support of object). For an object  $A = X_{a_1} \otimes \cdots \otimes X_{a_n}$ , define:

$$\text{supp}(A) = \{j : a_j \neq 0\} \quad (78)$$

(the set of factor positions that are nontrivial).

**Definition 14.11** ( $k$ -local morphism). A morphism  $\phi \in \text{Mor}(A, B)$  is  $k$ -local if the number of sites (factor positions) involved in the transition is at most  $k$ . Formally, this is satisfied if:

$$|\text{supp}(A) \cup \text{supp}(B)| \leq k \quad (79)$$

where  $A$  and  $B$  are viewed as objects on a local subset of sites.

*Remark 14.12* (Well-definedness and embedding). This definition is well-defined for *primitive* morphisms acting on a small number of anyons. When such a morphism is embedded into a larger lattice  $\Lambda$  with existing anyons at sites  $j \notin \text{supp}(A) \cup \text{supp}(B)$ , it is understood to act as the identity on those ‘spectator’ anyons. Thus, a 2-local hopping morphism remains 2-local even when acting on a many-particle state, as its non-trivial action is restricted to  $k = 2$  sites.

**Example 14.13.** •  $\text{Mor}(X_a \otimes X_b, X_c \otimes X_d)$  is 2-local: only factors 0 and 1 are involved.

- $\text{Mor}(X_a, X_a)$  is 1-local: only factor 0 is involved.
- $\text{Mor}(X_a \otimes \mathbf{1}, \mathbf{1} \otimes X_a)$  is 2-local: acts on positions 0 and 1.

*Remark 14.14.* In the context of lattice systems, locality also specifies which lattice sites the morphism acts on. This is covered when embedding into the lattice in §17.

## 15 Hard-Core vs Soft-Core Anyons

### 15.1 Hard-Core Constraint

**Definition 15.1** (Hard-core anyons). Anyons are *hard-core* if at most one anyon occupies each site:

$$x_1 < x_2 < \cdots < x_N \quad (80)$$

*Consequence 15.2.* Maximum particle number is  $N_{\max} = n$  (number of sites).

*Remark 15.3.* Hard-core is natural for:

- Impenetrable particles (infinite on-site repulsion)
- Lattice models where sites represent localised orbitals

### 15.2 Soft-Core: Multiple Occupancy

**Definition 15.4** (Soft-core anyons). Anyons are *soft-core* if multiple anyons may occupy the same site:

$$x_1 \leq x_2 \leq \cdots \leq x_N \quad (81)$$

**Definition 15.5** (On-site fusion space). When anyons  $X_a, X_b$  occupy the same site, the local state space is:

$$\bigoplus_c N_{ab}^c \cdot \text{Mor}(X_a \otimes X_b, X_c) \quad (82)$$

representing the possible fusion outcomes.

*Remark 15.6.* Soft-core requires tracking on-site fusion structure.

### 15.3 Hilbert Space Modifications

Regime	Config space	Local structure	$N_{\max}$
Hard-core	$x_i < x_j$ for $i < j$	One anyon/site	$n$
Soft-core	$x_i \leq x_j$ for $i < j$	Fusion at each site	$\infty$ (needs cutoff)

**Definition 15.7** (Hard-core Hilbert space).

$$\mathcal{H}^{\text{HC}} = \bigoplus_{N=0}^n \mathcal{H}_N^{\text{HC}} \quad (83)$$

where  $\mathcal{H}_N^{\text{HC}}$  uses  $\text{Conf}_N^{\text{HC}}$ .

### 15.4 Physical Motivation

**Hard-core regime:**

- Models impenetrable anyons
- Connection to Girardeau mapping (§???)
- Simpler Hilbert space structure

**Soft-core regime:**

- Models “bosonic” anyons that can bunch
- Richer on-site physics
- Connection to Levin–Wen models when particles can annihilate

**Convention 15.8.** Unless stated otherwise, we work in the **hard-core** regime.

## Part III

# Dynamics for Mobile Anyons

## 16 Matrix Elements of 2-Local Operators

**Planning ref:** §4.5

**Status:** Draft

**Assumptions.**

(A4.5.1) Fusion category  $\mathcal{C}$  with unit  $\mathbf{1}$  and simples  $X_0 = \mathbf{1}, X_1, \dots, X_{d-1}$ .

(A4.5.2) Hard-core constraint: at most one anyon per site.

(A4.5.3) Fusion tree basis fixed for  $\mathcal{H}_N^{(c)}$  (per Definition 13.13).

(A4.5.4) Multiplicity-free fusion rules (i.e.,  $N_{ab}^c \in \{0, 1\}$ ).

## 16.1 Fusion Trees as Basis Data

**Definition 16.1** (Fusion tree basis states). A fusion tree  $\tau$  (defined in Definition 13.13) specifies one of several basis choices for the morphism space  $\text{Mor}(X_c, \mathcal{O}(\mathbf{j}, \mathbf{k}))$ . We denote basis states as:

$$|(\mathbf{j}, \mathbf{k}), \tau, c\rangle \in \mathcal{H}_N^{(c)} \quad (84)$$

where:

- $(\mathbf{j}, \mathbf{k})$  is the configuration (site indices and anyon types)
- $\tau$  encodes the fusion tree structure
- $c$  is the total charge

*Remark 16.2.* The fusion tree is not canonical; different choices of parenthesisation yield different bases. For multiplicity-free categories, all choices span the same space, but individual basis vectors depend on the choice.

*Remark 16.3.* When two basis states have different fusion trees  $\tau \neq \tau'$  (even for the same configuration and charge), they are orthogonal basis vectors. The Gram matrix between them is determined by the F-symbols of the category.

## 16.2 Matrix Element Definitions

**Definition 16.4** (Matrix element for 2-local morphism). Given:

- Basis states  $|\psi\rangle = |(\mathbf{j}, \mathbf{k}), \tau, c\rangle$  and  $|\phi\rangle = |(\mathbf{j}', \mathbf{k}'), \tau', c\rangle$  in  $\mathcal{H}_N^{(c)}$
- A morphism  $f \in \text{Mor}(X_a \otimes X_b, X_c \otimes X_d)$  acting on sites  $m, m+1$

The matrix element is the complex number:

$$\langle \phi | f_{m,m+1} | \psi \rangle \in \mathbb{C} \quad (85)$$

Interpretation:  $f_{m,m+1}$  acts as a morphism between the anyon types at sites  $m, m+1$  in the source and target configurations.

## 16.3 Type 1: Two-Particle Interaction

**Definition 16.5** (Two-particle interaction morphism). A morphism  $f_{ab \rightarrow cd} \in \text{Mor}(X_a \otimes X_b, X_c \otimes X_d)$  acts on two neighbouring sites with anyons of type  $X_a, X_b$  and outputs  $X_c, X_d$ .

**Configuration support:** Non-zero matrix elements occur only when:

- Source configuration:  $s_m = a, s_{m+1} = b$
- Target configuration:  $s'_m = c, s'_{m+1} = d$
- All other sites identical:  $s_i = s'_i$  for  $i \notin \{m, m+1\}$
- Total charge preserved

In this case, the matrix element is:

$$\langle (\mathbf{j}', \mathbf{k}'), \tau' | f_{ab \rightarrow cd} | (\mathbf{j}, \mathbf{k}), \tau \rangle = \alpha_{ab \rightarrow cd}(\tau, \tau') \quad (86)$$

where  $\alpha_{ab \rightarrow cd}(\tau, \tau')$  is determined by the morphism and the fusion tree compatibility.

*Remark 16.6* (Multiplicity-free case).  $N_{ab}^c \in \{0, 1\}$  for all triples, so the morphism space  $\text{Mor}(X_a \otimes X_b, X_c \otimes X_d)$  is either  $\{0\}$  or one-dimensional. If non-zero, the coefficient  $\alpha_{ab \rightarrow cd}$  is a phase/scalar set by normalisation.

*Remark 16.7* (Forbidden fusion). If  $N_{ab}^c = 0$  (fusion forbidden), then  $\text{Mor}(X_a \otimes X_b, X_c) = \{0\}$ , and the operator component is identically zero.

**Claim 16.8** (Hermiticity). *If  $f_{ab \rightarrow cd}$  is a unitary morphism (or paired with its adjoint), the physical operator  $\mathcal{O} = f_{m,m+1} + f_{m,m+1}^\dagger$  is Hermitian and preserves the sector  $\mathcal{H}_N^{(c)}$ .*

## 16.4 Type 2: Right Hopping

**Definition 16.9** (Right-hopping morphism). A morphism  $h_R \in \text{Mor}(X_a \otimes \mathbf{1}, \mathbf{1} \otimes X_a)$  describes translating an anyon of type  $X_a$  from site  $m$  to site  $m + 1$ .

**Hard-core configuration support:**

- Source: anyon  $X_a$  at site  $m$ , vacuum ( $\mathbf{1}$ ) at site  $m + 1$
- Target: vacuum at site  $m$ , anyon  $X_a$  at site  $m + 1$

Matrix element:

$$\langle (\mathbf{j}', \mathbf{k}'), \tau' | h_{R,m,m+1} | (\mathbf{j}, \mathbf{k}), \tau \rangle = \begin{cases} \beta_a(\tau, \tau') & \text{if } s_m = a, s_{m+1} = 0 \text{ and } s'_m = 0, s'_{m+1} = a \\ 0 & \text{otherwise} \end{cases} \quad (87)$$

where  $\beta_a(\tau, \tau')$  is determined by the fusion tree evolution and normalisation convention.

**Claim 16.10** (Locality of hopping). *Right hopping is a 2-local operator: it couples only configurations differing by a single anyon displacement at neighbouring sites.*

## 16.5 Type 3: Left Hopping

**Definition 16.11** (Left-hopping morphism). A morphism  $h_L \in \text{Mor}(\mathbf{1} \otimes X_a, X_a \otimes \mathbf{1})$  describes translating an anyon of type  $X_a$  from site  $m + 1$  to site  $m$ .

**Hard-core configuration support:**

- Source: vacuum at site  $m$ , anyon  $X_a$  at site  $m + 1$
- Target: anyon  $X_a$  at site  $m$ , vacuum at site  $m + 1$

*Remark 16.12* (Relation to right hopping). By rigidity of the fusion category,  $h_L$  and  $h_R$  are related via duality. In particular, if both use consistent normalisation for  $X_a \otimes \mathbf{1} \leftrightarrow \mathbf{1} \otimes X_a$ , then  $h_L = h_R^\dagger$  (up to phase).

## 16.6 Operator Matrix Representation

**Definition 16.13** (Full operator matrix in  $\mathcal{H}_N^{(c)}$ ). Let  $\{|\psi_i\rangle = |(\mathbf{j}_i, \mathbf{k}_i), \tau_i, c\rangle\}_{i=1}^{d_N^{(c)}}$  be an orthonormal basis of  $\mathcal{H}_N^{(c)}$  (in a chosen fusion tree basis). The matrix representation of a 2-local operator  $\mathcal{O}$  is:

$$[\mathcal{O}]_{ij} := \langle \psi_i | \mathcal{O} | \psi_j \rangle \in \mathbb{C} \quad (88)$$

*Remark 16.14.* This is basis-dependent; different fusion tree bases yield different matrix coordinates. However, the eigenvalues and trace (and all basis-independent properties) are invariant.

**Claim 16.15** (Sparsity of 2-local operators). *For 2-local operators in the hard-core sector:*

- Type 1 (two-particle interaction) couples configurations with anyons at the same pair of sites  $(m, m + 1)$ ; expect  $O(n)$  nonzero entries per row.
- Type 2, 3 (hopping) couple configurations differing by a single displacement; expect  $O(1)$  nonzero entries per row.

Total matrix sparsity:  $O(n \cdot d_N^{(c)})$  nonzero entries.

## 16.7 Example: Two Fibonacci Anyons

**Example 16.16** (Fibonacci  $\tau$  anyons,  $N = 2$  on 3 sites). Fusion category: Fibonacci,  $d = 2$  (objects  $\mathbf{1}, \tau$ ),  $\tau \otimes \tau = \mathbf{1} \oplus \tau$  (multiplicity 1 each).

Hard-core configurations with 2 anyons on 3 sites:  $\text{Conf}_2^{\text{HC}}(3) = \{(0,1), (0,2), (1,2)\}$  (pairs of occupied sites).

Basis states in  $\mathcal{H}_2^{(1)}$  (two  $\tau$  anyons fusing to  $\mathbf{1}$ ):

- $|\psi_1\rangle = |(0,1), \tau, \mathbf{1}\rangle$  = anyons at sites 0, 1 fusing to  $\mathbf{1}$
- $|\psi_2\rangle = |(0,2), \tau, \mathbf{1}\rangle$  = anyons at sites 0, 2 fusing to  $\mathbf{1}$
- $|\psi_3\rangle = |(1,2), \tau, \mathbf{1}\rangle$  = anyons at sites 1, 2 fusing to  $\mathbf{1}$

Right-hopping operator  $h_{R,0,1}$  on sites 0, 1 (moves anyon from site 0 to site 1):

- Source: anyon at site 0, vacuum at site 1  $\rightarrow$  only  $|\psi_2\rangle = |(0,2)\rangle$  qualifies
- Target: vacuum at site 0, anyon at site 1  $\rightarrow$  only  $|\psi_3\rangle = |(1,2)\rangle$  qualifies
- Non-zero element:  $\langle\psi_3|h_{R,0,1}|\psi_2\rangle$

Matrix of  $h_{R,0,1}$  in basis  $\{\psi_1, \psi_2, \psi_3\}$ :

$$h_{R,0,1} = \begin{pmatrix} 0 & \beta & 0 \\ 0 & 0 & 0 \\ 0 & 0 & 0 \end{pmatrix} \quad (89)$$

where  $\beta$  is the amplitude (normalisation-dependent).

## 16.8 Critical Observations and Open Questions

**Observation 1** (Fusion tree dependence). The matrix elements explicitly depend on the choice of fusion tree basis via  $\tau, \tau'$ . This choice is not canonical for multiplicity  $N_{ab}^c > 1$ . All published definitions must remain basis-independent; fusion trees are a computational tool only.

**Observation 2** (Missing fusion tree reduction). Computing actual matrix elements requires:

1. Extracting the local fusion tree structure at sites  $j, j + 1$  from  $\tau$
2. Composing with the morphism  $f$  or  $h$
3. Tracking how  $\tau$  evolves to  $\tau'$
4. Applying R-matrices if the operator causes anyon braiding

This requires implementation of fusion tree reduction coefficients and F-symbols.

**Question 4.5.1** (Hard-core + arbitrary charge). For  $N$  anyons with definite charge  $c$  in hard-core sector, is the dimension of  $\mathcal{H}_N^{(c)}$  always  $O(\binom{n}{N})$ ? What are the constraints on  $c$ ?

**Question 4.5.2** (Multiplicity handling). How do matrix elements change if  $N_{ab}^c > 1$ ? Each morphism space becomes multi-dimensional, introducing index-dependent amplitudes  $\alpha_{ab \rightarrow cd}^{(\mu)}$ .

**Question 4.5.3** (Normalisation convention). What is the standard normalisation for  $h_R$  and  $h_L$ ? Should they be unitary? Hermitian? How does this interact with R-matrices and the fusion category structure?

## 17 Particle-Conserving Local Hamiltonians

**Planning ref:** §5.1.1

**Status:** Draft

### Assumptions.

- A5.1.1. Fusion category  $\mathcal{C}$  with unit  $\mathbf{1}$  and simples  $X_0 = \mathbf{1}, X_1, \dots, X_{d-1}$
- A5.1.2.  $n$  lattice sites labelled  $0, \dots, n-1$ , OBC
- A5.1.3. Hard-core regime: at most one anyon per site
- A5.1.4. Hilbert space  $\mathcal{H} = \bigoplus_{N=0}^n \mathcal{H}_N$  as in §4.2

### 17.1 Number-Conserving Hamiltonians (§5.1.1.1)

**Definition 17.1** (Number operator). The *number operator*  $\hat{N} : \mathcal{H} \rightarrow \mathcal{H}$  acts as

$$\hat{N} |\psi\rangle = N |\psi\rangle \quad \text{for } |\psi\rangle \in \mathcal{H}_N \quad (90)$$

**Definition 17.2** (Number-conserving Hamiltonian). A Hamiltonian  $H$  is *number-conserving* (or *particle-conserving*) if it commutes with the number operator:

$$[\hat{N}, H] = 0 \quad (91)$$

Equivalently,  $H$  preserves each  $N$ -particle sector:

$$H : \mathcal{H}_N \rightarrow \mathcal{H}_N \quad \text{for all } N \in \{0, 1, \dots, n\} \quad (92)$$

*Remark 17.3.* Number-conserving Hamiltonians do not create or annihilate anyons. They may move existing anyons between sites or introduce interactions between them.

### 17.2 Local Hamiltonians (§5.1.1.2)

**Definition 17.4** (Local Hamiltonian). A Hamiltonian  $H$  is *local* if it decomposes as

$$H = \sum_{j=0}^{n-2} h_j \quad (93)$$

where each  $h_j$  acts nontrivially only on a bounded neighbourhood of site  $j$ .

**Definition 17.5** (Nearest-neighbour Hamiltonian). A Hamiltonian  $H$  is *nearest-neighbour* if each local term  $h_j$  acts nontrivially only on sites  $j$  and  $j+1$ :

$$h_j : \mathcal{H} \rightarrow \mathcal{H}, \quad h_j = \mathbb{1}_{<j} \otimes \tilde{h}_j \otimes \mathbb{1}_{>j+1} \quad (94)$$

where  $\tilde{h}_j$  acts on the two-site space.

### 17.3 Morphism Decomposition (§5.1.1.3)

For mobile anyons, local terms decompose into morphism spaces. A number-conserving, nearest-neighbour term  $h_j$  has components:

**Definition 17.6** (Morphism components of local term). A nearest-neighbour term  $h_j$  acting on sites  $j, j+1$  decomposes as:

$$h_j \in \bigoplus_{A,B} \text{Mor}(A, B) \quad (95)$$

where  $A, B$  are objects of the form  $X_a \otimes X_b$  with  $a, b \in \{0, 1, \dots, d-1\}$ , and the sum is over pairs  $(A, B)$  with equal numbers of nontrivial (non-vacuum) factors.

**Proposition 17.7** (Number conservation criterion). *A local term  $h_j$  is number-conserving if and only if for every nonzero component in  $\text{Mor}(X_a \otimes X_b, X_c \otimes X_d)$ :*

$$|\{a, b\} \cap \{1, \dots, d-1\}| = |\{c, d\} \cap \{1, \dots, d-1\}| \quad (96)$$

where  $|S|$  denotes the count of indices in  $S$  that are nonzero (nontrivial).

## 17.4 Classification of Two-Site Processes (§5.1.1.4)

For hard-core anyons, the possible two-site configurations and number-conserving transitions are:

Source $X_a \otimes X_b$	Target $X_c \otimes X_d$	Process	Particle count
$1 \otimes 1$	$1 \otimes 1$	Vacuum identity	0
$X_a \otimes 1$	$1 \otimes X_a$	Hop right	1
$1 \otimes X_a$	$X_a \otimes 1$	Hop left	1
$X_a \otimes 1$	$X_a \otimes 1$	Stay left	1
$1 \otimes X_a$	$1 \otimes X_a$	Stay right	1
$X_a \otimes X_b$	$X_a \otimes X_b$	Two-anyon identity	2
$X_a \otimes X_b$	$X_c \otimes X_d$	Two-anyon scattering	2

*Remark 17.8.* Note that hopping does NOT involve braiding: the anyon moves to an empty site without passing through another anyon. Braiding processes are treated in §5.1.3.

## 17.5 Hermiticity (§5.1.1.5)

**Definition 17.9** (Hermitian local term). A local term  $h_j$  is *Hermitian* if  $h_j = h_j^\dagger$ .

For morphism components, this means:

$$\langle B | h_j | A \rangle = \overline{\langle A | h_j | B \rangle} \quad (97)$$

where the bar denotes complex conjugation.

**Proposition 17.10** (Hermiticity in terms of morphisms). *A local term with component  $\alpha \in \text{Mor}(A, B)$  is Hermitian if and only if it also has component  $\alpha^\dagger \in \text{Mor}(B, A)$  with matching coefficient.*

## 17.6 Laplacian-Type Models (§5.1.1.2)

The simplest number-conserving Hamiltonians are *tight-binding* or *Laplacian-type* models, where anyons hop freely between adjacent sites.

### 17.6.1 Single-Particle Sector

**Definition 17.11** (Anyonic discrete Laplacian). The *anyonic discrete Laplacian* on the single-particle sector  $\mathcal{H}_1$  is:

$$H_{\text{Lap}} = -t \sum_{j=0}^{n-2} \sum_{a=1}^{d-1} (|j+1; a\rangle \langle j; a| + |j; a\rangle \langle j+1; a|) \quad (98)$$

where  $t > 0$  is the hopping amplitude and  $|j; a\rangle$  denotes a single anyon of type  $X_a$  at site  $j$ .

*Remark 17.12.* In the single-particle sector, there is no distinction between anyonic and bosonic behaviour: a lone anyon hops without braiding or fusion interactions. The Laplacian preserves the anyon type  $a$ .

**Proposition 17.13** (Spectrum of single-particle Laplacian). *For OBC on  $n$  sites, the single-particle Laplacian has spectrum:*

$$E_k = -2t \cos\left(\frac{\pi k}{n+1}\right), \quad k = 1, \dots, n \quad (99)$$

with eigenstates:

$$|\psi_k; a\rangle = \sqrt{\frac{2}{n+1}} \sum_{j=0}^{n-1} \sin\left(\frac{\pi k(j+1)}{n+1}\right) |j; a\rangle \quad (100)$$

Each energy level has  $(d-1)$ -fold degeneracy corresponding to anyon types.

### 17.6.2 Multi-Particle Sector with Hard-Core Constraint

For  $N > 1$  anyons in the hard-core regime, hopping is only permitted to empty adjacent sites.

**Definition 17.14** (Hard-core hopping term). The nearest-neighbour hopping term at bond  $(j, j+1)$  for hard-core anyons is:

$$h_j^{\text{hop}} = -t \sum_{a=1}^{d-1} \left( P_j^{(0)} \otimes P_{j+1}^{(a)} \rightarrow P_j^{(a)} \otimes P_{j+1}^{(0)} \right) + \text{h.c.} \quad (101)$$

where  $P_m^{(a)}$  projects onto anyon type  $X_a$  at site  $m$ , and  $X_0 = \mathbf{1}$  is the vacuum.

*Remark 17.15.* In morphism language, the hopping term has components in  $\text{Mor}(\mathbf{1} \otimes X_a, X_a \otimes \mathbf{1})$  and its adjoint. For the vacuum object  $\mathbf{1}$ , these morphism spaces are one-dimensional (canonical isomorphisms from the unit constraints), so the hopping amplitude is unambiguous.

**Definition 17.16** (Hard-core tight-binding Hamiltonian). The *hard-core tight-binding Hamiltonian* is:

$$H_{\text{TB}} = \sum_{j=0}^{n-2} h_j^{\text{hop}} \quad (102)$$

This Hamiltonian conserves particle number and respects the hard-core constraint.

### 17.6.3 Diagrammatic Representation

The hopping term can be represented diagrammatically as:

The dashed line represents the vacuum  $\mathbf{1}$ , and the solid line represents an anyon of type  $X_a$ .

### 17.6.4 Connection to Standard Models

**Proposition 17.17** (Bosonic limit). *For the category  $\text{Vec}$  (trivial fusion category with one simple object),  $H_{\text{TB}}$  reduces to the standard hard-core boson tight-binding model:*

$$H_{\text{TB}} = -t \sum_j \left( b_j^\dagger b_{j+1} + b_{j+1}^\dagger b_j \right) (1 - n_j n_{j+1}) \quad (103)$$

where the  $(1 - n_j n_{j+1})$  factor enforces hard-core exclusion.

**Proposition 17.18** (Fermionic limit). *For the category  $\mathbf{sVec}$  (super-vector spaces), with appropriate sign conventions,  $H_{\text{TB}}$  reduces to the spinless fermion tight-binding model:*

$$H_{\text{TB}} = -t \sum_j (c_j^\dagger c_{j+1} + c_{j+1}^\dagger c_j) \quad (104)$$

The hard-core constraint is automatic due to Pauli exclusion.

*Remark 17.19.* These limiting cases demonstrate that the anyonic tight-binding model correctly interpolates between bosonic and fermionic physics in appropriate limits.

## 17.8 Summary

## 17.9 Next Steps

- §5.1.1.3: Hard-core blocking behaviour
- §5.1.2: Interactions without braiding
- §5.1.3: Free anyons with braiding

Concept	Symbol	Definition
Number operator	$\hat{N}$	Counts anyons: $\hat{N} \psi\rangle = N \psi\rangle$ for $ \psi\rangle \in \mathcal{H}_N$
Number-conserving	$[\hat{N}, H] = 0$	Preserves particle number
Nearest-neighbour	$h_j$	Acts on sites $j, j+1$ only
Morphism component	$\text{Mor}(A, B)$	Transitions between local configurations
Anyonic Laplacian	$H_{\text{Lap}}$	Free hopping on single-particle sector
Tight-binding	$H_{\text{TB}}$	Hard-core hopping on multi-particle sector

## 18 Interactions Without Braiding

**Planning ref:** §5.1.2

**Status:** Draft

Building on the particle-conserving framework of §17, we now introduce *interaction terms* that act nontrivially when two anyons occupy adjacent sites. These interactions preserve particle number and do not involve braiding—the anyons remain in place but their internal fusion channel may change.

### Assumptions.

We inherit all assumptions from §17: fusion category  $\mathcal{C}$  with simples  $X_0 = \mathbf{1}, X_1, \dots, X_{d-1}$ ,  $n$  lattice sites with OBC, and hard-core regime.

### 18.1 Interactions in $\text{Mor}(X_a \otimes X_b, X_c \otimes X_d)$ (§5.1.2.1)

When two anyons occupy adjacent sites  $j$  and  $j+1$ , the local configuration is described by  $X_a \otimes X_b$  for some non-vacuum simple objects  $X_a, X_b \in \{X_1, \dots, X_{d-1}\}$ .

**Definition 18.1** (Two-anyon interaction space). The *two-anyon interaction space* at bond  $(j, j+1)$  with anyon types  $(a, b)$  and  $(c, d)$  is:

$$\mathcal{I}_{ab}^{cd} := \text{Mor}(X_a \otimes X_b, X_c \otimes X_d) \quad (105)$$

where  $a, b, c, d \in \{1, \dots, d-1\}$  are non-vacuum indices.

**Proposition 18.2** (Dimension of interaction space). *The dimension of the interaction space is:*

$$\dim \mathcal{I}_{ab}^{cd} = \sum_e N_{ab}^e N_{cd}^e \quad (106)$$

where  $N_{ab}^e$  are the fusion coefficients and the sum is over all simple objects  $X_e$ .

*Proof.* By the definition of morphism spaces in a fusion category:

$$\text{Mor}(X_a \otimes X_b, X_c \otimes X_d) \cong \bigoplus_e \text{Mor}(X_a \otimes X_b, X_e) \otimes \text{Mor}(X_e, X_c \otimes X_d) \quad (107)$$

Since  $\dim \text{Mor}(X_a \otimes X_b, X_e) = N_{ab}^e$  and  $\dim \text{Mor}(X_e, X_c \otimes X_d) = N_{cd}^e$ , the result follows.  $\square$

*Remark 18.3.* For the diagonal case  $a = c$  and  $b = d$ , the interaction space  $\mathcal{I}_{ab}^{ab}$  always contains the identity morphism. Additional morphisms exist when  $\sum_e (N_{ab}^e)^2 > 1$ .

### 18.1.1 Fusion Channel Basis

The interaction space has a natural basis indexed by intermediate fusion channels.

**Definition 18.4** (Fusion channel projector). For simple objects  $X_a, X_b$  with  $N_{ab}^e \geq 1$ , the *fusion channel projector* onto channel  $X_e$  is:

$$P_{ab}^e : X_a \otimes X_b \rightarrow X_a \otimes X_b \quad (108)$$

defined diagrammatically as:

This is the composition of the splitting morphism  $X_a \otimes X_b \rightarrow X_e$  with the fusion morphism  $X_e \rightarrow X_a \otimes X_b$ .

**Proposition 18.5** (Projector properties). *The fusion channel projectors satisfy:*

1. *Idempotent:*  $(P_{ab}^e)^2 = d_e^{-1} P_{ab}^e$  (with quantum dimension normalisation)
2. *Orthogonal:*  $P_{ab}^e \circ P_{ab}^{e'} = 0$  for  $e \neq e'$
3. *Complete:*  $\sum_e d_e P_{ab}^e = X_a \otimes X_b$

## 18.2 Particle Number Conservation (§5.1.2.2)

**Definition 18.6** (Number-conserving interaction). An interaction term  $h_j^{\text{int}}$  at bond  $(j, j+1)$  is *number-conserving* if it has components only in spaces  $\mathcal{I}_{ab}^{cd}$  where both  $(a, b)$  and  $(c, d)$  consist of non-vacuum labels.

**Proposition 18.7** (Number conservation for interactions). *A two-anyon interaction preserves particle number automatically: both the source  $X_a \otimes X_b$  and target  $X_c \otimes X_d$  have exactly two particles (since  $a, b, c, d \neq 0$ ).*

*Remark 18.8.* Unlike hopping terms (which connect one-particle to one-particle configurations via vacuum), interaction terms cannot change the particle number by construction. The constraint is that we only consider  $\text{Mor}(X_a \otimes X_b, X_c \otimes X_d)$  with all non-vacuum indices.

## 18.3 Exclusion of Braiding (§5.1.2.3)

In this section, we consider only *local* interactions that do not involve the braiding structure of the category.

**Definition 18.9** (Non-braiding interaction). An interaction morphism  $f \in \text{Mor}(X_a \otimes X_b, X_c \otimes X_d)$  is *non-braiding* if it can be expressed purely in terms of:

- Fusion morphisms:  $\iota_{ab}^e : X_a \otimes X_b \rightarrow X_e$
- Splitting morphisms:  $\pi_{cd}^e : X_e \rightarrow X_c \otimes X_d$
- The associator  $\alpha$
- Unit constraints  $\lambda, \rho$

without using the braiding isomorphism  $\sigma_{X,Y} : X \otimes Y \rightarrow Y \otimes X$ .

**Proposition 18.10** (Non-braiding interaction basis). *The non-braiding interactions in  $\text{Mor}(X_a \otimes X_b, X_c \otimes X_d)$  are spanned by morphisms of the form:*

$$\pi_{cd}^e \circ \iota_{ab}^e : X_a \otimes X_b \xrightarrow{\iota} X_e \xrightarrow{\pi} X_c \otimes X_d \quad (109)$$

for fusion channels  $X_e$  with  $N_{ab}^e \geq 1$  and  $N_{cd}^e \geq 1$ .

*Remark 18.11.* The exclusion of braiding means that we cannot permute the spatial order of anyons. The anyon on the left stays on the left, and the anyon on the right stays on the right. Only their internal labels (types) may change through the fusion–splitting process.

### 18.3.1 Diagrammatic Interpretation

A non-braiding interaction has the following diagrammatic form:

The two incoming strands fuse into an intermediate channel  $X_e$ , which then splits into two outgoing strands. Note that no crossing of strands occurs.

## 18.4 Examples and Physical Interpretation (§5.1.2.4)

### 18.4.1 Fibonacci Anyons

For Fibonacci anyons, the category has two simple objects:  $\mathbf{1}$  (vacuum) and  $\tau$  (Fibonacci anyon), with fusion rule  $\tau \otimes \tau = \mathbf{1} \oplus \tau$ .

**Example 18.12** (Fibonacci interaction). The interaction space  $\text{Mor}(\tau \otimes \tau, \tau \otimes \tau)$  has dimension:

$$\dim \text{Mor}(\tau \otimes \tau, \tau \otimes \tau) = N_{\tau\tau}^{\mathbf{1}} N_{\tau\tau}^{\mathbf{1}} + N_{\tau\tau}^{\tau} N_{\tau\tau}^{\tau} = 1 \cdot 1 + 1 \cdot 1 = 2 \quad (110)$$

The two basis elements are:

1.  $P^{\mathbf{1}}$ : Projection onto the vacuum fusion channel
2.  $P^{\tau}$ : Projection onto the  $\tau$  fusion channel

A general Hermitian interaction takes the form:

$$h_j^{\text{int}} = J_{\mathbf{1}} P_j^{\mathbf{1}} + J_{\tau} P_j^{\tau} \quad (111)$$

where  $J_{\mathbf{1}}, J_{\tau} \in \mathbb{R}$  are coupling constants.

*Remark 18.13.* This is precisely the interaction structure of the golden chain model [FTLM07]. The ground state properties depend on the ratio  $J_{\tau}/J_{\mathbf{1}}$ .

### 18.4.2 Ising Anyons

The Ising category has three simple objects:  $\mathbf{1}$ ,  $\sigma$ ,  $\psi$  with fusion rules:

$$\sigma \otimes \sigma = \mathbf{1} \oplus \psi, \quad \sigma \otimes \psi = \sigma, \quad \psi \otimes \psi = \mathbf{1} \quad (112)$$

**Example 18.14** (Ising  $\sigma$ - $\sigma$  interaction). For two  $\sigma$  anyons:

$$\dim \text{Mor}(\sigma \otimes \sigma, \sigma \otimes \sigma) = 1 + 1 = 2 \quad (113)$$

with projectors  $P^{\mathbf{1}}$  and  $P^{\psi}$  onto the vacuum and fermion channels.

**Example 18.15** (Ising  $\sigma$ - $\psi$  interaction). For a  $\sigma$  and  $\psi$  anyon:

$$\dim \text{Mor}(\sigma \otimes \psi, \sigma \otimes \psi) = 1 \quad (114)$$

The only interaction is the identity—no nontrivial interaction is possible because the fusion  $\sigma \otimes \psi = \sigma$  has a unique channel.

### 18.4.3 Type Conversion

**Definition 18.16** (Type-converting interaction). A *type-converting interaction* is a morphism in  $\text{Mor}(X_a \otimes X_b, X_c \otimes X_d)$  with  $(a, b) \neq (c, d)$ .

**Example 18.17** (Ising type conversion). In the Ising category,  $\text{Mor}(\sigma \otimes \sigma, \psi \otimes \psi)$  has a non-zero component if there exists  $X_e$  with  $N_{\sigma\sigma}^e \geq 1$  and  $N_{\psi\psi}^e \geq 1$ . Since:

$$\sigma \otimes \sigma = \mathbf{1} \oplus \psi, \quad \psi \otimes \psi = \mathbf{1} \quad (115)$$

we have  $N_{\sigma\sigma}^1 = N_{\psi\psi}^1 = 1$ , so:

$$\dim \text{Mor}(\sigma \otimes \sigma, \psi \otimes \psi) = 1 \quad (116)$$

This morphism converts a pair of  $\sigma$  anyons into a pair of  $\psi$  anyons via the vacuum channel.

## 18.5 General Interaction Hamiltonian

**Definition 18.18** (Two-body interaction Hamiltonian). A *two-body interaction Hamiltonian* without braiding takes the form:

$$H_{\text{int}} = \sum_{j=0}^{n-2} h_j^{\text{int}} \quad (117)$$

where each local term is:

$$h_j^{\text{int}} = \sum_{a,b,c,d=1}^{d-1} \sum_{e: N_{ab}^e, N_{cd}^e \geq 1} J_{abcd}^e (\pi_{cd}^e \circ \iota_{ab}^e)_j \quad (118)$$

with coupling constants  $J_{abcd}^e \in \mathbb{C}$ .

**Proposition 18.19** (Hermiticity condition).  $H_{\text{int}}$  is Hermitian if and only if:

$$J_{abcd}^e = \overline{J_{cdab}^e} \quad (119)$$

for all valid indices.

## 18.6 Combined Hamiltonian

**Definition 18.20** (Hopping-plus-interaction Hamiltonian). The *v1 Hamiltonian* combines hopping (from §17) with interactions:

$$H_{v1} = H_{\text{TB}} + H_{\text{int}} = \sum_{j=0}^{n-2} \left( h_j^{\text{hop}} + h_j^{\text{int}} \right) \quad (120)$$

This is the most general particle-conserving, nearest-neighbour Hamiltonian that does not involve braiding.

*Remark 18.21.* The v1 Hamiltonian describes mobile anyons that can hop between adjacent sites and interact when two anyons meet. The hopping is unrestricted (any anyon can hop to an empty neighbour), while interactions occur only between pairs of anyons at adjacent sites.

## 18.7 Matrix Elements

For explicit computations, we express the interaction terms using F-symbols.

**Proposition 18.22** (F-symbol matrix elements). *In the fusion tree basis (see §6), the matrix element of the fusion channel projector  $P_{ab}^e$  is:*

$$\langle f_1, \dots, f_{n-1} | P_{ab}^e | f_1, \dots, f'_{n-1} \rangle = \delta_{f_j, e} \delta_{f'_j, e} \cdot (\text{F-symbol factors}) \quad (121)$$

where  $f_j$  is the fusion channel at bond  $(j, j+1)$ .

*Remark 18.23.* The detailed F-symbol expressions depend on the normalisation conventions chosen for the fusion/splitting morphisms. See §?? for the general framework.

## 18.8 Summary

Concept	Symbol	Description
Interaction space	$\mathcal{I}_{ab}^{cd}$	$\text{Mor}(X_a \otimes X_b, X_c \otimes X_d)$
Fusion projector	$P_{ab}^e$	Projects onto channel $e$
Non-braiding	—	No use of $\sigma_{X,Y}$
Type-converting	—	$(a, b) \neq (c, d)$
v1 Hamiltonian	$H_{v1}$	Hopping + interaction

## 18.9 Next Steps

- §5.1.3: Free anyons with braiding—permuting anyon positions
- §5.2: Symmetries and conserved quantities

## 19 Free Anyons with Braiding

**Planning ref:** §5.1.3

**Status:** Draft

This section introduces dynamics where anyons can *pass through each other* via the braiding structure of the category. Unlike the hard-core models of §17–18, where anyons at adjacent sites either hop to empty sites or interact without exchanging positions, here we allow genuine exchange processes mediated by R-moves.

## Assumptions.

We inherit assumptions from §17 with one crucial addition:

A5.1.3.1. The fusion category  $\mathcal{C}$  is **braided**, with braiding isomorphisms  $c_{X,Y} : X \otimes Y \xrightarrow{\sim} Y \otimes X$  satisfying the hexagon equations.

### 19.1 Anyons Passing via Braiding (§5.1.3.1)

In a braided fusion category, two anyons can exchange positions through the braiding morphism. This is fundamentally different from hopping (movement to an empty site) or fusion-splitting (interaction without position change).

**Definition 19.1** (Exchange morphism). For simple objects  $X_a, X_b$ , the *exchange morphism* is the braiding:

$$c_{X_a, X_b} : X_a \otimes X_b \xrightarrow{\sim} X_b \otimes X_a \quad (122)$$

This is an isomorphism (invertible morphism) with inverse  $c_{X_a, X_b}^{-1} = c_{X_b, X_a}^{-1}$ .

*Remark 19.2.* The braiding  $c_{X_a, X_b}$  is **not** the same as  $c_{X_b, X_a}^{-1}$  in general. For a symmetric category (bosons),  $c_{X_a, X_b} = c_{X_b, X_a}^{-1}$ . For non-symmetric braided categories (true anyons), these differ—this is the origin of anyonic statistics.

#### 19.1.1 Physical Interpretation

When anyon  $X_a$  at site  $j$  exchanges with anyon  $X_b$  at site  $j+1$ :

- **Before:** Configuration is  $\dots \otimes X_a \otimes X_b \otimes \dots$  (anyon  $a$  left of anyon  $b$ )
- **After:** Configuration is  $\dots \otimes X_b \otimes X_a \otimes \dots$  (anyon  $b$  left of anyon  $a$ )
- **Amplitude:** The transition amplitude is given by the R-symbols

**Definition 19.3** (R-symbol). The *R-symbol*  $R_{ab}^c$  is the matrix element of the braiding in the fusion tree basis:

$$c_{X_a, X_b} |a, b; c; \mu\rangle = \sum_{\nu} (R_{ab}^c)_{\mu\nu} |b, a; c; \nu\rangle \quad (123)$$

where  $|a, b; c; \mu\rangle$  denotes a state with anyons  $X_a, X_b$  fusing to channel  $X_c$  with multiplicity index  $\mu$ .

**Proposition 19.4** (R-symbol properties). *The R-symbols satisfy:*

1. **Unitarity:**  $(R_{ab}^c)^\dagger R_{ab}^c = \mathbb{1}$
2. **Hexagon equations:** Consistency with F-moves (see §3)
3. **For multiplicity-free fusion:**  $R_{ab}^c$  is a phase  $e^{i\theta_{ab}^c}$

### 19.2 Hamiltonian with R-Moves (§5.1.3.2)

We now construct Hamiltonians that include exchange terms using the braiding.

**Definition 19.5** (Exchange term). The *exchange term* at bond  $(j, j+1)$  is:

$$h_j^{\text{ex}} = \sum_{a,b=1}^{d-1} \tau_{ab} (c_{X_a, X_b})_j + \text{h.c.} \quad (124)$$

where  $\tau_{ab} \in \mathbb{C}$  are exchange amplitudes and  $(c_{X_a, X_b})_j$  acts on sites  $j, j+1$ .

*Remark 19.6.* The exchange term is automatically number-conserving: it permutes two anyons without creating or destroying particles.

**Definition 19.7** (Free anyon Hamiltonian). The *free anyon Hamiltonian* combines hopping, interactions, and exchange:

$$H_{\text{free}} = H_{\text{TB}} + H_{\text{int}} + H_{\text{ex}} \quad (125)$$

where:

- $H_{\text{TB}}$  is the tight-binding (hopping) Hamiltonian from §17
- $H_{\text{int}}$  is the interaction Hamiltonian from §18
- $H_{\text{ex}} = \sum_j h_j^{\text{ex}}$  is the exchange Hamiltonian

### 19.2.1 Soft-Core Regime

With braiding, we can also consider *soft-core* anyons where multiple particles can occupy the same site.

**Definition 19.8** (Soft-core exchange). In the soft-core regime, the local Hilbert space at each site includes superpositions of anyon types. The exchange term acts as:

$$h_j^{\text{ex}} : \mathcal{H}_j \otimes \mathcal{H}_{j+1} \rightarrow \mathcal{H}_{j+1} \otimes \mathcal{H}_j \quad (126)$$

implementing a “SWAP” operation twisted by the R-symbols.

### 19.2.2 Matrix Elements

**Proposition 19.9** (Exchange matrix elements). *In the fusion tree basis, the exchange term has matrix elements:*

$$\langle f_1, \dots, f_{n-1} | h_j^{\text{ex}} | f'_1, \dots, f'_{n-1} \rangle = \tau_{a_j, a_{j+1}} \cdot R_{a_j, a_{j+1}}^{f_j} \cdot \delta_{f_k, f'_k}^{k \neq j} \quad (127)$$

where  $a_j, a_{j+1}$  are the anyon types at sites  $j, j+1$  and  $f_j$  is the fusion channel at bond  $j$ .

*Proof.* The braiding acts locally at bond  $(j, j+1)$ , changing the order of anyons  $X_{a_j} \otimes X_{a_{j+1}} \mapsto X_{a_{j+1}} \otimes X_{a_j}$ . In the fusion tree basis, this transformation is diagonal in the fusion channel  $f_j$  (since  $X_{a_j} \otimes X_{a_{j+1}}$  and  $X_{a_{j+1}} \otimes X_{a_j}$  fuse to the same channels), with the R-symbol as coefficient.  $\square$

## 19.3 Diagrammatic Representation (§5.1.3.3)

The exchange term has a simple diagrammatic form: a crossing of two strands.

### 19.3.1 Over-Crossing and Under-Crossing

**Convention 19.10** (Crossing convention). We use the convention that an *over-crossing* (left strand passes over right) represents  $c_{X_a, X_b}$ , and an *under-crossing* represents  $c_{X_a, X_b}^{-1}$ .

### 19.3.2 Exchange in the Fusion Tree Basis

When the anyons are part of a longer chain with definite fusion channels, the exchange involves R-symbols:

The fusion channel  $e$  is preserved, but the amplitude acquires a factor of  $R_{ab}^e$ .

## 19.4 Boson and Fermion Limits (§5.1.3.4)

The braided anyon framework correctly reproduces bosonic and fermionic statistics in appropriate limits.

### 19.4.1 Bosonic Limit: $\text{Vec}$

**Proposition 19.11** (Bosonic exchange). *For the category  $\text{Vec}$  (ordinary vector spaces), the braiding is trivial:*

$$c_{V,W} : V \otimes W \xrightarrow{\sim} W \otimes V, \quad v \otimes w \mapsto w \otimes v \quad (128)$$

All R-symbols are  $R_{ab}^c = 1$ .

**Corollary 19.12.** *In the  $\text{Vec}$  limit, the exchange Hamiltonian reduces to a symmetric SWAP:*

$$h_j^{\text{ex}} = \tau \cdot \text{SWAP}_j \quad (129)$$

where  $\text{SWAP}_j$  exchanges the states at sites  $j$  and  $j + 1$  with no phase.

### 19.4.2 Fermionic Limit: $\text{sVec}$

**Proposition 19.13** (Fermionic exchange). *For the category  $\text{sVec}$  (super-vector spaces) with simple objects  $\mathbf{1}$  (even/bosonic) and  $f$  (odd/fermionic), the braiding is:*

$$c_{f,f} : f \otimes f \rightarrow f \otimes f, \quad c_{f,f} = -\text{id}_{f \otimes f} \quad (130)$$

The R-symbol for two fermions is  $R_{ff}^1 = -1$ .

**Corollary 19.14.** *In the  $\text{sVec}$  limit, exchanging two fermions introduces a minus sign:*

$$h_j^{\text{ex}} | \dots, f, f, \dots \rangle = -\tau | \dots, f, f, \dots \rangle \quad (131)$$

This is the hallmark of Fermi statistics.

*Remark 19.15.* The fermionic sign is automatic from the categorical structure—no additional sign factors need to be inserted by hand (compare with Jordan–Wigner transformations in spin chain approaches).

### 19.4.3 Anyonic Statistics: Fibonacci Example

**Example 19.16** (Fibonacci R-symbols). For Fibonacci anyons with  $\tau \otimes \tau = \mathbf{1} \oplus \tau$ , the R-symbols are:

$$R_{\tau\tau}^{\mathbf{1}} = e^{-4\pi i/5}, \quad R_{\tau\tau}^{\tau} = e^{3\pi i/5} \quad (132)$$

These are neither +1 (bosonic) nor -1 (fermionic)—they are genuine anyonic phases.

*Remark 19.17.* The two different R-symbols for the two fusion channels reflect the non-abelian nature of Fibonacci anyons: the exchange phase depends on which fusion channel the pair is in.

### 19.4.4 Ising Anyons

**Example 19.18** (Ising R-symbols). For Ising anyons with  $\sigma \otimes \sigma = \mathbf{1} \oplus \psi$ :

$$R_{\sigma\sigma}^{\mathbf{1}} = e^{-i\pi/8}, \quad R_{\sigma\sigma}^{\psi} = e^{3i\pi/8} \quad (133)$$

The  $\psi$  particle (fermion) has  $R_{\psi\psi}^{\mathbf{1}} = -1$ .

## 19.5 Full Classification of Two-Site Processes

Combining hopping (§17), interactions (§18), and exchange, we obtain the complete set of number-conserving processes:

Process	Morphism space	Requires braiding?	Section
Vacuum identity	$\text{Mor}(\mathbf{1} \otimes \mathbf{1}, \mathbf{1} \otimes \mathbf{1})$	No	§5.1.1
Hop right	$\text{Mor}(\mathbf{1} \otimes X_a, X_a \otimes \mathbf{1})$	No	§5.1.1
Hop left	$\text{Mor}(X_a \otimes \mathbf{1}, \mathbf{1} \otimes X_a)$	No	§5.1.1
Two-anyon interaction	$\text{Mor}(X_a \otimes X_b, X_c \otimes X_d)$	No	§5.1.2
Two-anyon exchange	$c_{X_a, X_b} : X_a \otimes X_b \rightarrow X_b \otimes X_a$	Yes	§5.1.3

Table 2: Classification of number-conserving two-site processes.

## 19.6 Summary

Concept	Symbol	Description
Braiding	$c_{X,Y}$	Isomorphism $X \otimes Y \rightarrow Y \otimes X$
R-symbol	$R_{ab}^c$	Matrix element of braiding in fusion basis
Exchange term	$h_j^{\text{ex}}$	Hamiltonian term for anyon exchange
Free anyon Hamiltonian	$H_{\text{free}}$	Hopping + interaction + exchange

## Basic Properties of the Models

### 20 Module Categories

**Assumptions.**

- (A1) Fusion category  $\mathcal{C}$  over  $\mathbb{C}$  (from §??).
- (A2)  $\mathcal{C}$  is rigid (has duals).
- (A3) Module categories are semisimple and finite.

#### 20.1 Overview

*Module categories* provide the mathematical framework for classifying boundary conditions in topological phases. A (left)  $\mathcal{C}$ -module category is a category  $\mathcal{M}$  equipped with an action of the fusion category  $\mathcal{C}$ , analogous to how a module is a set with an action of a ring.

In the context of anyonic chains, module categories classify:

- Boundary conditions for open chains
- Edge modes and boundary excitations
- Domain walls between different phases

#### 20.2 Definition of Module Categories

**Definition 20.1** (Left module category). A *left  $\mathcal{C}$ -module category* is a category  $\mathcal{M}$  equipped with:

1. **Action functor:**  $\triangleright : \mathcal{C} \times \mathcal{M} \rightarrow \mathcal{M}$ , written  $(X, M) \mapsto X \triangleright M$ .
2. **Module associator:** Natural isomorphism

$$m_{X,Y,M} : (X \otimes Y) \triangleright M \xrightarrow{\sim} X \triangleright (Y \triangleright M). \quad (134)$$

3. **Unit constraint:** Natural isomorphism  $\ell_M : \mathbf{1} \triangleright M \xrightarrow{\sim} M$ .

These satisfy coherence conditions (pentagon and triangle diagrams for modules).

**Definition 20.2** (Right module category). A *right  $\mathcal{C}$ -module category* is defined analogously with action  $\triangleleft : \mathcal{M} \times \mathcal{C} \rightarrow \mathcal{M}$ .

**Definition 20.3** (Bimodule category). A  *$(\mathcal{C}, \mathcal{D})$ -bimodule category* is a category  $\mathcal{M}$  that is simultaneously a left  $\mathcal{C}$ -module and right  $\mathcal{D}$ -module, with compatible associators.

*Reference:* Etingof–Nikshych–Ostrik, *Adv. Math.* **226** (2011) [unverified]

#### 20.3 Simple Module Objects

**Definition 20.4** (Simple module object). An object  $M \in \mathcal{M}$  is *simple* if it has no proper subobjects. The simple objects of  $\mathcal{M}$  form a finite set  $\text{Irr}(\mathcal{M})$ .

*Remark 20.5.* Simple module objects correspond to *boundary excitations* or *edge modes*—the elementary degrees of freedom localised at the boundary.

## 20.4 Internal Hom

**Definition 20.6** (Internal Hom). For  $M, N \in \mathcal{M}$ , the *internal Hom*  $\underline{\text{Hom}}(M, N) \in \mathcal{C}$  is defined by:

$$\text{Hom}_{\mathcal{M}}(X \triangleright M, N) \cong \text{Hom}_{\mathcal{C}}(X, \underline{\text{Hom}}(M, N)). \quad (135)$$

This captures how bulk anyons ( $X \in \mathcal{C}$ ) can transform one boundary excitation into another.

## 20.5 The Regular Module

**Example 20.7** (Regular module). Every fusion category  $\mathcal{C}$  is a module over itself via the tensor product:

$$X \triangleright Y := X \otimes Y. \quad (136)$$

This is called the *regular module*  $\mathcal{C}_{\mathcal{C}}$ .

The regular module corresponds to the “trivial” or “smooth” boundary condition.

## 20.6 Module Functors

**Definition 20.8** (Module functor). A  $\mathcal{C}$ -module functor between  $\mathcal{C}$ -module categories  $\mathcal{M}$  and  $\mathcal{N}$  is a functor  $F : \mathcal{M} \rightarrow \mathcal{N}$  with natural isomorphisms:

$$s_{X,M} : F(X \triangleright M) \xrightarrow{\sim} X \triangleright F(M) \quad (137)$$

satisfying coherence conditions.

Module functors describe *boundary-changing operators* or *defects* between different boundary conditions.

## 20.7 Morita Equivalence

**Definition 20.9** (Morita equivalence). Two fusion categories  $\mathcal{C}$  and  $\mathcal{D}$  are *Morita equivalent* if there exists an invertible  $(\mathcal{C}, \mathcal{D})$ -bimodule category.

**Theorem 20.10** (Boundary-bulk correspondence). *The bulk topological order determines, and is determined by, the set of all possible boundary conditions (module categories) up to Morita equivalence.*

Reference: Kitaev–Kong, *Commun. Math. Phys.* **313** (2012), 351–373 [unverified]

# 21 Boundary Conditions for Anyonic Chains

## Assumptions.

- (A1) Bulk fusion category  $\mathcal{C}$  (from §??).
- (A2) 1D chain with open boundary conditions (from §11).
- (A3) Boundary conditions classified by  $\mathcal{C}$ -module categories.

## 21.1 Overview

For anyonic chains with open boundary conditions, the choice of *boundary conditions* at each end significantly affects the Hilbert space structure and dynamics. Following the Kitaev–Kong framework, boundary conditions are classified by *module categories* over the bulk fusion category  $\mathcal{C}$ .

Different boundary conditions lead to different edge mode structures, affecting ground state degeneracy, edge excitations, and partition functions.

## 21.2 Boundary Hilbert Space

**Definition 21.1** (Boundary Hilbert space). For a chain with:

- Bulk category  $\mathcal{C}$
- Left boundary condition  $\mathcal{M}_L$  (left  $\mathcal{C}$ -module category)
- Right boundary condition  $\mathcal{M}_R$  (right  $\mathcal{C}$ -module category)

The boundary-modified Hilbert space involves the *relative tensor product*  $\mathcal{M}_L \boxtimes_{\mathcal{C}} \mathcal{M}_R$ .

## 21.3 Trivial Boundary Conditions

**Definition 21.2** (Trivial/smooth boundary). The *trivial boundary condition* corresponds to the regular module  $\mathcal{C}_{\mathcal{C}}$ , where  $\mathcal{C}$  acts on itself by tensor product.

Anyons can freely approach the boundary without restriction. No edge modes beyond the bulk structure.

## 21.4 Gapped Boundaries via Lagrangian Algebras

**Definition 21.3** (Lagrangian algebra). A *Lagrangian algebra*  $A \in \mathcal{C}$  is a commutative algebra object satisfying:

$$\dim(A)^2 = \dim(\mathcal{C}), \quad (138)$$

where  $\dim(\mathcal{C}) = \sum_i d_i^2$  is the total quantum dimension.

**Theorem 21.4** (Classification of gapped boundaries). *Gapped boundary conditions for a topological phase with bulk  $\mathcal{C}$  are in bijection with Lagrangian algebras in  $\mathcal{C}$  (for modular  $\mathcal{C}$ ).*

*Reference:* Kong–Wen, JHEP (2014) [unverified]

A Lagrangian algebra specifies which bulk anyons can “condense” at the boundary.

## 21.5 Examples

**Example 21.5** (Fibonacci anyons). For the Fibonacci category  $\mathcal{C} = \text{Fib}$  with simples  $\{\mathbf{1}, \tau\}$ :

Module category	Simple objects	Physical meaning
FibFib (regular)	$\{\mathbf{1}, \tau\}$	Smooth boundary
Vec (condensed)	$\{\mathbf{1}\}$	$\tau$ condensed at boundary

**Example 21.6** (Ising anyons). For the Ising category  $\mathcal{C} = \text{Ising}$  with simples  $\{\mathbf{1}, \sigma, \psi\}$ :

Module category	Simple objects	Physical meaning
Ising <sub>Ising</sub>	$\{\mathbf{1}, \sigma, \psi\}$	Smooth boundary
Vec( $\mathbb{Z}_2$ )	$\{\mathbf{1}, \psi\}$	$\sigma$ condensed

## 21.6 Application to Mobile Anyons

For mobile anyons on an open chain (our setting from §13):

1. **Standard construction** (§13): Uses trivial boundary conditions implicitly.
2. **With general boundaries:** The Hilbert space becomes:

$$\mathcal{H} = \bigoplus_{M_L \in \mathcal{M}_L} \bigoplus_{M_R \in \mathcal{M}_R} \mathcal{H}(M_L, M_R), \quad (139)$$

where  $\mathcal{H}(M_L, M_R)$  is the space of bulk configurations interpolating between boundary states.

3. **Boundary Hamiltonians:** Additional terms can describe:

- Boundary potentials (energy cost for edge modes)
- Boundary-bulk coupling (anyons interacting with edge)
- Boundary-changing operators (transitions between boundary conditions)

## 21.7 Connection to Golden Chain

**Example 21.7** (Golden chain boundaries). The golden chain (Fibonacci anyons at unit filling) has been studied with various boundary conditions:

- **Free boundaries:** Regular module, leading to CFT edge modes.
- **Fixed boundaries:** Specific module object pinned at edge, breaking some symmetry.
